Abstract

This paper deals with distributed reinforcement learning problems with safety constraints. In particular, we consider that a team of agents cooperate in a shared environment, where each agent has its individual reward function and safety constraints that involve all agents’ joint actions. As such, the agents aim to maximize the team-average long-term return, subject to all the safety constraints. More intriguingly, no central controller is assumed to coordinate the agents, and both the rewards and constraints are only known to each agent locally/privately. Instead, the agents are connected by a peer-to-peer communication network to share information with their neighbors. In this work, we first formulate this problem as a distributed constrained Markov decision process (D-CMDP) with networked agents. Then, we propose a decentralized policy gradient (PG) method, Safe Dec-PG, to perform policy optimization based on this D-CMDP model over a network. Convergence guarantees, together with numerical results, showcase the superiority of the proposed algorithm. To the best of our knowledge, this is the first decentralized PG algorithm that accounts for the coupled safety constraints with a quantifiable convergence rate in the multi-agent reinforcement learning. Finally, we emphasize that our algorithm is also novel in solving general decentralized stochastic nonconvex-concave minimax optimization problems, where both the algorithm design and corresponding theoretical analysis are of independent interest.

Introduction

Reinforcement learning (RL) has achieved tremendous success in many sequential decision-making problems in (Mnih et al. 2015; Sutton and Barto 2018), such as operations research, optimal control, bounded rationality, machine learning, etc., where an agent explores the interactions with an environment so that it can be used to accumulate a cumulative reward through this learning process. Beyond applying the classical RL techniques in control systems, physical con-
excluding (strongly) convex and non-convex cases. Recent advances in distributed non-convex optimization show that decentralized stochastic gradient descent or tracking (DSGD/DSGT) is able to train neural networks much faster than the centralized algorithms in terms of running time numerically (Lian et al. 2017; Lu et al. 2019). Also, it has been indicated in theory that there is a linear speed-up of performing decentralized optimization compared with the centralized one in terms of the number of nodes (Lian et al. 2017; Tang et al. 2018; Lu and Wu 2020). Moreover, in practice, the data would be collected through the sensors over a network, so the distributed learning becomes one of the most signal, data, and information processing tools. (Please see a survey (Chang et al. 2020) of recent distributed non-convex optimization algorithms and their applications.) However, the safe RL problem is not only maximizing rewards but also takes practical issues into account or introduces some prior knowledge of the model in advance, where there would be multiple cumulative long-term reward functions incorporated as the constraints (Paternain et al. 2019a; Wachi and Sui 2020). Unfortunately, none of the existing works deal with the safety constraints that are also non-convex, no need to mention their distributed implementation over a network.

By the primal-dual optimization framework, the safe RL problem can be formulated as a min-max saddle point form by the method of Lagrange multipliers or dualizing the constraints (Boyd and Vandenberghe 2004). However, different from the classical supervised learning, e.g., support vector machine and least squares regression, the policy in RL is mostly parametrized by a (deep) neural network so that the cumulative reward functions are non-convex. Hence, the duality gap in this case is not zero in general, which makes the optimization process much more difficult than the traditional convex-concave min-max problem even in the centralized setting. Interestingly, some recent exciting results illustrate that the duality gap in safe RL problems could be zero (Paternain et al. 2019b) by assuming some oracle that can find the global optimal solution of the Lagrangian with respect to policy. It is inspiring that safe RL might be solved efficiently to high-quality solutions by the non-convex min-max solvers.

During the last few years, solving non-convex min-max saddle-point problems has gained huge popularity and indicated significant power of optimizing the interest of parameters in many machine learning and/or artificial intelligence problems, including adversarial learning, robust neural nets or generative adversarial nets (GANs) training, fair resource allocation (Razaviyayn et al. 2020). The main idea of designing these algorithms is to perform gradient descent and ascent with respect to the objective functions, such as gradient descent ascent (GDA) algorithm (Lin, Jin, and Jordan 2019), multi-GDA (Nouiehed et al. 2019), proximal guided stochastic mirror descent method (PGSMD) (Rafique et al. 2018), and hybrid block successive approximation (HiBSA) (Lu et al. 2020). The difference between GDA and multi-GDA is that the latter performs multiple steps of gradient ascent updates instead of one. Among these algorithms, HiBSA achieves the fastest convergence rate with only a single loop update rule to optimization variables for the deterministic non-convex case. However, there is no theoretical guarantee that HiBSA is amenable to handle the stochasticity of the samples in the non-convex (strongly) concave min-max problems. Further, all these algorithms are centralized, so it is not clear whether they can be used for a multi-agent system. Recently, there are some interesting works regarding the distributed training for a class of GANs (Liu et al. 2019b, 2020), where the problem is formulated as a decentralized non-convex saddle-point problem. But both of them require that the objective function satisfy the Minty variational inequality (MVI), otherwise, these methods cannot converge to an ε-first-order stationary point (FOSP) of the considered problem even the number of iterations is infinite. While in RL/MARL there is no evidence which can indicate that discounted cumulative reward function satisfies MVI again due to the nonconvexity of the loss function when the policy at each node is parametrized by a neural net.

### Main contributions

In this work, by leveraging the min-max saddle-point formulation, we propose the first safe decentralized policy gradient (PG) descent and ascent algorithm, i.e., Safe Dec-PG, which is able to deal with a class of multi-agent safe RL problems over a graph. Importantly, we provide theoretical results that quantify the convergence rate of Safe Dec-PG to an ε-first-order stationary points (FOSP) of the considered non-convex min-max problem in the order of $1/\epsilon^4$ (or equivalently the optimality gap is shrinking in the order of $1/\sqrt{N}$, where $N$ denotes the total number of iterations). When the graph is fully connected in the sense that there is no consensus error (each agent can know all the other agents’ policy at each iteration), Safe Dec-PG will reduce to a centralized algorithm. Even in this case, the obtained convergence rate is still the state-of-the-art result to the best of our knowledge. A more detailed comparison between proposed Safe Dec-PG and other existing stochastic non-convex concave min-max algorithm in the centralized setting is shown in Table 1.

### Table 1: A comparison of stochastic non-convex concave minmax algorithms with convergence to (a neighborhood of) first-order stationary points (FOSPs).

main advantages of Safe Dec-PG are highlighted as follows:

- **Simplicity** The structure of implementing the algorithm is single-loop, where the parameters that need to be tuned are only the stepizes in the minimization and maximization subproblems.
- **(Theoretical Guarantees)** It is theoretically provable that Safe Dec-PG is able to find the an $\epsilon$-FOSP of the formulated min-max problem within $O(1/\epsilon^3)$ number of iterations, matching the standard convergence rate of centralized stochastic gradient descent (SGD) and decentralized SGD to $\epsilon$-FOSPs in non-convex scenarios.
- **(Applicability)** Safe Dec-PG is also a general optimization problem solver, which can be applied for dealing with many non-convex min-max problems rather than the RL/MARL problems, and it could be implemented in either a decentralized way over a network or on a single machine.

Multiple numerical results showcase the superiority of the algorithms applied in the problems of safe decentralized RL compared with the classic decentralized methods without safety considerations. Due to the page limitation, proofs of all the lemmas, the main theorem and additional numerical results are included in the supplemental materials.

**Safe MARL with Decentralized Agents**

In this section, we introduce the background and formulation of the safe MARL problem with decentralized agents.

**Multi-agent constrained Markov decision process (M-CMDP)**

Consider a team of $n$ agents operating in a common environment, denoted by $\mathcal{N} = [n]$. No central controller exists to either make the decisions or collect any information for the agents. Agents are instead allowed to communicate with each other over a communication network $\mathcal{G} = (\mathcal{N}, \mathcal{E})$, with $\mathcal{E}$ being the set of communication links that connect the agents. Such a decentralized model with networked agents finds broad applications in distributed cooperative control problems (Faux and Murray 2004; Corke, Peterson, and Rus 2005; Dall’Anese, Zhu, and Giannakis 2013), and has been advocated as one of the most popular paradigms in decentralized MARL (Zhang et al. 2018; Wai et al. 2018; Doan, Maguluri, and Romberg 2019; Qu et al. 2019; Zhang, Yang, and Basar 2019; Lee et al. 2019). More importantly, each agent has some safety constraints, in the forms of bounds on some long term cost, that involve the joint policy of all agents. We formally introduce the following model of networked multi-agent constrained MDP (M-CMDP) to characterize this setting.

**Definition 1** *(Networked Multi-agent CMDP (M-CMDP)).* A networked multi-agent CMDP is described by a tuple $(S, \{A_i\}_{i \in \mathcal{N}}, P, \{R_i\}_{i \in \mathcal{N}}, \mathcal{G}, \{C_i\}_{i \in \mathcal{N}}; \gamma)$ where $S$ is the state space shared by all the agents, $A_i$ is the action space of agent $i$, and $\mathcal{G}$ is a communication network (a well-connected graph). Let $A = \prod_{i=1}^{n} A_i$ be the joint action space of all agents; then, $R_i : S \times A \rightarrow \mathbb{R}$ and $C_i : S \times A \rightarrow \mathbb{R}$ are the local rewards and cost functions of agent $i$, and $P : S \times A \times S \rightarrow [0, 1]$ is the state transition probability of the MDP. $\gamma \in (0, 1)$ denotes the discount factor. The states $s$ and actions $a$ are globally observable, while the rewards and costs are observed locally/privately at each agent.

The networked M-CMDP proceeds as follows. At time $t$, each agent $i$ chooses its own action $a_i^t$ given $s^t$, according to its local policy $\pi_i : S \rightarrow \Delta(A_i)$, which is usually parametrized as $\pi_{w_i}$ by some parameter $w_i \in \Theta_i$ with dimension $d_i$. The networked agents try to learn a joint policy $\pi : S \rightarrow \Delta(A)$ given by $\pi_{w, \theta} \triangleq \prod_{i \in \mathcal{N}} \pi_{w_i} \circ \mathcal{G}_{\theta_i}$ with $\theta = [\theta_1^\top \ldots \theta_n^\top]^\top \in \mathbb{R}^d$, where $d = \sum_{i=1}^{n} d_i$ denotes the whole problem dimension. As a team, the objective of all agents is to collaboratively maximize the globally average return over the network (equivalently to minimize the opposite of it), dictated by $R_{\theta}(s, a) = n^{-1} \sum_{i \in \mathcal{N}} R_i(s, a_i)$, with only its local observations of the rewards, subject to some safety constraints dictated by $C_i(s, a)$. At each node, there would be multiple safety constraints. These rewards describe different objectives that the agent is required to achieve, such as remaining with a region of the state space, or not running out of memory/battery. Here, we assume that each agent is associated with $m$ cost functions, so $C_i(s, a)$ is a mapping from $S \times A$ to $\mathbb{R}^m$. Specifically, the team aims to find the joint policy $\pi_{\theta}$ that

$$\min_{\theta \in \Theta} J^{R}_{\theta}(\theta) \triangleq \mathbb{E} \left( -\frac{1}{n} \sum_{t \geq 0} \gamma^t \sum_{i \in \mathcal{N}} R_i(s^t, a_i^t) \mid s^0, \pi_{\theta} \right)$$ (1a)

subject to:

$$J^{C}_{\theta}(\theta) \triangleq \mathbb{E} \left( \sum_{t \geq 0} \gamma^t C_i(s^t, a_i^t) \mid s^0, \pi_{\theta} \right) \geq c_i, \forall i \in \mathcal{N}$$ (1b)

where $\Theta = \prod_{i=1}^{n} \Theta_i$ is the joint policy parameter space, $J^{R}_{\theta}(\theta)$ corresponds to the team-average discounted long-term return, $J^{C}_{\theta}(\theta) : \mathbb{R}^d \rightarrow \mathbb{R}^m$ denotes the long-term costs of agent $i$, $c_i \in \mathbb{R}^m$, $\forall i$ are the lower-bounds of $J^{C}_{\theta}(\theta)$, $\forall i$ that impose the safety constraints, and $\mathbb{E}$ is taken over all randomness including the policy and the underlying Markov chain. Each agent $i$ only has access to its own reward and cost $R_i$ and $C_i$, and the desired bound $c_i$. Note that our ensuing results can be straightforwardly generalized to the setting where each agent has different number of costs, at the expense of unnecessarily complicated notations. In general, the long-term return $J^{R}_{\theta}(\theta)$ is non-convex with respect to the policy parameter $\theta$ (Zhang et al. 2019a; Liu et al. 2019b; Agarwal et al. 2019), so do the constraint functions $J^{C}_{\theta}(\theta), \forall i$, which makes the problem challenging to solve using the first-order PG methods.

**Primal-dual for safe M-CMDP**

Viewing the team as a single agent, the problem above falls into the regime of the standard constrained MDP (Altman 1999), which has been widely studied in single-agent safe RL. Nonetheless, in a decentralized paradigm, standard RL algorithms for solving CMDP are not applicable, as they require the instantaneous access to the team-average reward and all cost functions $\{C_i\}_{i \in \mathcal{N}}$ (Borkar 2005; Prashanth and Ghavamzadeh 2016; Achiam et al. 2017; Yu et al. 2019; Paternain et al. 2019b). Instead, we re-formulate the problem as a decentralized non-convex optimization problem with non-
convex constraints, in order to develop decentralized policy optimization algorithms. In particular, letting $J_i^R(\theta) \triangleq \mathbb{E}(-\sum_{t\geq 0} \gamma^t R_i(s^t, a^t') | s^0, \pi_\theta)$, we have the networked M-CMDP as

$$\min_{\theta \in \Theta} \frac{1}{n} \sum_{i \in N} J_i^R(\theta_i)$$  \hspace{1cm} (2)

s.t. $\theta_i = \theta_j \quad j \in N_i, \quad c_i - J_i^C(\theta_i) \leq 0, \quad \forall i \in N,$

where $N_i \subseteq N$ denotes the set of the neighboring agents of agent $i$ over the network, and $\theta_i$ is the local copy of the policy parameter $\theta$ (i.e., the concatenation of all the agents’ parameters). By the duality theory (Boyd and Vandenberghe 2004), the problem (2) can be written as

$$\min_{\theta \in \Theta} \max_{\lambda \geq 0} L(\theta_1, \ldots, \theta_n, \lambda_1, \ldots, \lambda_n)$$  \hspace{1cm} (3a)

s.t. $\theta_i = \theta_j \quad j \in N_i, \quad \forall i,$

where

$$L(\theta_1, \ldots, \theta_n, \lambda_1, \ldots, \lambda_n) \triangleq \frac{1}{n} \sum_{i \in N} J_i^R(\theta_i) + \langle g_i(\theta_i), \lambda_i \rangle,$$

$$g_i(\theta_i) \triangleq c_i - J_i^C(\theta_i),$$

and $\lambda_1, \ldots, \lambda_n$ denote the dual variables.

**Main challenges of solving safe decentralized RL**

To this end, the multi-agent safe RL problem has been formulated as (3). Unfortunately, there is no existing work that is able to solve this problem to its FOSP’s with any theoretical guarantees. The main difficulties here are four-fold as follows:

- There are two types of constraints that are both appeared in this problem: one is the consensus equality constraint and the other one is the long term cumulative reward related inequality constraint.
- The constraints and loss functions are both in an expected discounted cumulative reward form and possibly non-convex, while most of the classical non-convex algorithms, e.g., neural nets training, are designed for the case where only the loss functions are non-convex.
- The problem is stochastic in nature and the PG estimate is biased instead of unbiased due to the finite-horizon approximation, so we need extra efforts to quantify how biased estimates affect the convergence results.
- From a min-max saddle-point perspective, the minimization problem is non-convex and the maximization problem is concave (linear), while there would be also a consensus error coupled with both minimization and maximization optimization variables. Disentangling this error from the minimization and maximization processes will result in a significant different theorem proving technique compared with the existing theoretical works.

Therefore, solving this family of stochastic non-convex problems over a graph is much more challenging than the classical ones, e.g., centralized min-max saddle-point problems, decentralized consensus problems, stochastic non-convex problems, and so on. Next, we will propose the new gradient tracking based single loop primal dual algorithm to deal with this M-CMDP problem.

**Safe M-CMDP Algorithm**

First, we introduce the safe policy gradient used in Safe Dec-PG as the following.

**Safe policy gradient**

The search for an optimal policy can thus be performed by applying the gradient descent-type iterative methods to the parametrized optimization problem (3). The gradient of each agent’s cumulative loss $J_i^R(\theta_i)$ in (3) can be written as (Baxter and Bartlett 2001)

$$\nabla_{\theta_i} J_i^R(\theta_i) = \mathbb{E} \left[ \sum_{t=0}^{\infty} \nabla \log \pi_i(a_t^* | s_t^*; \theta_i) \gamma^t R_i(s_t^*, a_t^*) \right]$$

where $\{a_t^*, s_t^*\}$ are obtained from each trajectory under the joint policy (parametrized by $\{\theta_i, \forall i\}$). When the MDP model is unknown, the stochastic estimate of PG is often used, that is

$$\hat{\nabla}_{\theta_i} J_i^R(\theta_i) = \sum_{t=0}^{\infty} \nabla \log \pi_i(a_t^* | s_t^*; \theta_i) \gamma^t R_i(s_t^*, a_t^*),$$

which was proposed in (Baxter and Bartlett 2001) and called the gradient of a partially observable MDP (abbreviated as G(P)MDP PG). The G(P)MDP gradient is an unbiased estimator of the PG (Papini et al. 2018; Xu, Gao, and Gu 2020).

Likewise, the stochastic PG estimate of each agent’s $J_i^C(\theta_i)$ in (3) can be written as

$$\hat{\nabla}_{\theta_i} J_i^C(\theta_i) = \sum_{t=0}^{\infty} \nabla \log \pi_i(a_t^* | s_t^*; \theta_i) \gamma^t C_i(s_t^*, a_t^*).$$

Let $f_i(\theta_i, \lambda_i) \triangleq J_i^R(\theta_i) + \langle c_i - J_i^C(\theta_i), \lambda_i \rangle, \forall i$ for notational simplicity. Then, the policy gradients with respect to primal variables are

$$\hat{\nabla}_{\theta_i} f_i(\theta_i, \lambda_i) = \hat{\nabla}_{\theta_i} J_i^R(\theta_i) - \langle \hat{\nabla}_{\theta_i} J_i^C(\theta_i), \lambda_i \rangle, \forall i$$  \hspace{1cm} (5)

and the policy gradients with respect to dual variables are

$$\hat{\nabla}_{\lambda_i} f_i(\theta_i, \lambda_i) = c_i - J_i^C(\theta_i), \forall i$$  \hspace{1cm} (6)

where $J_i^C(\theta_i) \triangleq \sum_{t=0}^{\infty} \gamma^t C_i(s_t^*, a_t^* | s_0^*, \pi_\theta)$. Note that the stochastic gradients in (5) and (6) use only one trajectory of the Markov chain, which may incur large variance. Akin to mini-batch in SGD, a natural solution is to average over $K$ trajectories to obtain the policy gradient with respect to the primal variables denoted as $\hat{\nabla}_{\theta_i} f_i(\theta_i, \lambda_i), \forall i$, and with respect to the dual variables denoted as $\hat{\nabla}_{\lambda_i} f_i(\theta_i, \lambda_i), \forall i$. In simulations, sampling an infinite trajectory may not be tractable, and a finite-horizon approximation of the PGs (5) and (6) is usually used (Chen et al. 2018), which are denoted as $\hat{\nabla}_{\theta_i} f_i(\theta_i, \lambda_i)$ and $\hat{\nabla}_{\lambda_i} f_i(\theta_i, \lambda_i)$. Also, we can have a set of globally observable states and actions denoted by $\{s^*_k, a^*_k\}$, where $k$ denotes the index of trajectories and $\tau$ denotes the index of time. Consequently, the stochastic
estimate of PG with $K$ trajectories (samples) and a finite-horizon truncation of length $T$ can be expressed as
\[
\hat{\nabla}^{T,K}_{\theta_i} f_i(\theta_i, \lambda_i) = \nabla^{T,K}_{\theta_i} J_{i}^{R}(\theta_i) - \langle \hat{\nabla}^{T,K}_{\theta_i} J_{i}^{C}(\theta_i), \lambda_i \rangle, \tag{7a}
\]
\[
\hat{\nabla}^{T,K}_{\lambda_i} f_i(\theta_i, \lambda_i) = c_i - (\hat{J}^{C}_{i})^{T,K}(\theta_i) \triangleq \bar{g}_i(\theta_i) \tag{7b}
\]
where
\[
\hat{\nabla}^{T,K}_{\theta_i} J_{i}^{R}(\theta_i) \triangleq \frac{1}{K} \sum_{k=1}^{K} \sum_{t=0}^{T} \nabla \log \pi(a_{i,k}^{t+1}|s_{i}^{t}; \theta_i) \nabla^T R_i(s_{i}^{t}, a_{i}^{t}), \tag{8}
\]
\[
\hat{\nabla}^{T,K}_{\lambda_i} J_{i}^{C}(\theta_i) \triangleq \frac{1}{K} \sum_{k=1}^{K} \sum_{t=0}^{T} \left( \sum_{t=0}^{T} \nabla \log \pi(a_{i,k}^{t+1}|s_{i}^{t}; \theta_i) \nabla^T C_i(s_{i}^{t}, a_{i}^{t}) \right), \tag{9}
\]
and $(\hat{J}^{C}_{i})^{T,K}(\theta_i) \triangleq K^{-1} \sum_{k=1}^{K} \sum_{t=0}^{T} \nabla^T C_i(s_{i}^{t}, a_{i}^{t})$. Note that the finite length horizontal truncation will make the stochastic estimate PG become biased.

**Safe Dec-PG: Safe decentralized policy gradient**

After getting the PG estimates, Safe Dec-PG algorithm we proposed is given below. For notational simplicity, in the following we assume the problem dimension is 1. We first update the parameters of the parametrized policy at each node by
\[
\theta_{i}^{r+1} = \sum_{j \in N_i} W_{ij} \theta_j - \beta^r \theta_i^r, \tag{10}
\]
where $r$ denotes the index of the iterations, $\beta^r$ is the stepsize of PG descent, $\theta^r_i$ is an auxiliary (tracking) variable (which will be introduced with more details later in (11)), and $W_{ij}$ is a weight matrix that characterizes the relations among the nodes over graph $G$.

Next, we provide detailed descriptions about $W$ and $\theta$: 1) The weight matrix is double stochastic (i.e., the graph is well-connected), as follows: if there exists a link between node $i$ and node $j$, then $W_{ij} > 0$, otherwise $W_{ij} = 0$, and $W$ satisfies $W1 = 1$ and $1^T W = 1^T$. There are many ways of designing the weight matrix based on the connectivity of the graph. The standard ones include Metropolis-Hasting weight, maximum-degree weight, Laplacian weight (Xiao and Boyd 2004; Boyd, Diaconis, and Xiao 2004); 2) due to the partial observability of each agent, the variable $\theta^r_i$ here is proposed for approximating the full PG of the network (i.e., $\sum_{i=1}^{n} \sum_{i=1}^{n} W_{ij}$, where $W_{ij}$ is the coupling matrix), and is updated locally as
\[
\theta_{i}^{r+1} = \sum_{j \in N_i} W_{ij} \theta_j + \hat{\nabla}^{T,K}_{\theta_i} f_i(\theta_i^{r+1}, \lambda_i^r) - \hat{\nabla}^{T,K}_{\theta_i} f_i(\theta_i^{r}, \lambda_i^r), \forall i \tag{11}
\]
with $\theta_{i}^{0} \triangleq 0, \forall i$. This update rule is similar to the (stochastic) gradient tracking technique proposed for both classical consensus based (deterministic or stochastic) distributed optimization problems (Di Lorenzo and Scutari 2016; Sun, Daneshmand, and Scutari 2019). But here since we also have dual variable updates, at each time the evaluated gradient is also dependent on $\lambda_i^r$, so it is not clear whether the tracked full PG by $\theta_i^r$ is still accurate enough so that the resulting sequence can converge to the stationary points of problem (3). In our performance analysis section, we will show the conditions that can ensure the convergence of Safe Dec-PG in solving problem (3).

In this work, instead of performing a vanilla dual update, we propose to add a (quadratic) perturbation term (a.k.a. smoothing technique) to the maximization procedure as follows:
\[
\lambda_{i}^{r+1} = \arg \max_{\lambda_{i} \geq 0} \left\langle \hat{\nabla}^{T,K}_{\theta_i} f_i(\theta_i^{r+1}, \lambda_i^r), \lambda_i - \lambda_i^r \right\rangle - \frac{1}{2\rho} \lambda_i^2 - \frac{\gamma^r}{2} \parallel \lambda_i \parallel^2, \forall i \tag{12}
\]
where $\rho > 0$ is the stepsize of PG ascent in updating $\lambda_i^r$, $\gamma^r$ (to be defined later) is a diminishing parameter. The perturbation term $\gamma^r/2 \parallel \lambda_i \parallel^2$ plays one of the most key roles of ensuring the convergence of Safe Dec-PG. It adds some (desired) curvature to this subproblem (12) in such a way it is possible to quantify the maximum ascent of our constructed potential function (a Lyapunov-like function that will be used to measure the progress of the proposed algorithm) after the update of $\lambda_i^r$. Then, this parameter gradually reduces the problem curvature to resemble the original subproblem such that the obtained solution is the FOSP of problem (3) rather a deviated one. Note that (12) can also be easily implemented locally by
\[
\lambda_i^{r+1} = \mathcal{P}_\Lambda \left( (1 - \rho \gamma^r) \lambda_i^r + \rho \hat{\nabla}^{T,K}_{\theta_i} f_i(\theta_i^{r+1}, \lambda_i^r) \right), \quad \forall i \tag{13}
\]
where $\mathcal{P}_\Lambda$ denotes the projection operator, and $\Lambda = \{ \lambda_i | \lambda_i \geq 0 \}$ stands for the feasible set.

**Algorithm 1 Safe Dec-PG**

```
Input: $\theta_0^0, \theta_0^0 = \lambda_0^0 = 0, \forall i$
for $r = 1, \ldots$ do
    for Each agent $i$ do
        Update $\theta_i^{r+1}$ by (10)
        Perform rollout to get $\hat{\nabla}^{T,K}_{\theta_i} f_i(\theta_i^{r+1}, \lambda_i^r)$
        Update $\theta_i^{r+1}$ by (11)
        Calculate $(\hat{J}^{C}_{i})^{T,K}(\theta_i^{r+1})$
        Update $\lambda_i^{r+1}$ by (13)
    end for
end for
```

It can be seen that one of the major advantages of Safe Dec-PG is regarding its simplicity of updating rules for all the parameters: 1) a single loop algorithm; 2) each variable can be only updated locally through exchanging the parameters over the communication channel. From the following convergence analysis, we will show that when some mild conditions hold, Safe Dec-PG is guaranteed to find the FOSP of problem (3) by controlling the stepsizes used in the minimization and maximization procedures properly.
Performance Analysis of Safe Dec-PG

Before showing our theoretical results, we first give the standard assumptions as follows.

Assumptions

To begin with, we assume that $f_i, g_i, \forall i$ satisfy a Lipschitz continuous condition. To be more specific, we have

Assumption 1. Assume functions $\nabla f_i(\theta_i, \lambda_i), \forall i$ have $L_i$-Lipschitz continuity with respect to $\theta_i, \forall i$ and functions $g_i(\theta_i), \forall i$ have $L_i'$-Lipschitz continuity with respect to $\theta_i, \forall i$.

Next, we assume the connectivity of the graph, which specifies the topology of the communication channel so that the consensus step can be performed in a decentralized way.

Assumption 2. Assume the network is well-connected (a.k.a. strongly-connected), i.e., $\mathbf{W}$ is a double stochastic matrix. Also $\lambda_{\text{max}}(\mathbf{W}) \triangleq \eta < 1$, where $\lambda_{\text{max}}(\mathbf{W})$ denotes the second largest eigenvalue of the weight matrix $\mathbf{W}$.

Assumption 3. We assume that the rewards in both objective and constraints are upper bounded by $G$, i.e., \[ \max \{ R_i(\mathbf{s}^i, \mathbf{a}^i), C_i(\mathbf{s}^i, \mathbf{a}^i), \forall i \} \leq G, \] and the true PG is upper bounded by $G'$, i.e., \[ \| \nabla \log \pi_i(\mathbf{a}^i | \mathbf{s}^i; \theta_i) \| \leq G', \forall i, \tau. \]

The first part of Assumption 3 requires the boundedness of the instantaneous reward, which makes sense in practice since the physical systems commonly output finite magnitudes of responses. The second part requires the partial derivatives of the log function of the policies, i.e., \[ \| \nabla \log \pi_i(\mathbf{a}^i | \mathbf{s}^i; \theta_i) \| \] to be bounded, which can be satisfied by e.g., parametrized Gaussian policies.

Assumption 4. Assume that the Slater condition is satisfied and the size of $\Lambda$ is upper bounded by $\sigma_{\Lambda}$.

It is known that when the Slater condition (feasibility) is satisfied (Nedić and Ozdaglar 2009)[Lemma 1], the size of dual variable is upper bounded.

Convergence Rate

Since functions $J^P_i$ and $J^C_i, \forall i$ are possibly non-convex, finding the global optimal solution for this min-max problem is NP-hard in general (Nouiehed, Lee, and Razaviyayn 2018). It is of interest to obtain the FOSPs of problem (1). First, we define the optimality gap as

\[ G(\{ \theta_i, \lambda_i, \forall i \}) = \left\| \frac{1}{n} \sum_{i=1}^n \nabla f_i(\theta_i, \lambda_i) \right\| \]

\[ + \frac{1}{n} \sum_{i=1}^n \| \lambda_i - \mathcal{P}_\Lambda [\lambda_i + g_i(\lambda_i)] \| + \frac{1}{n} \sum_{i=1}^n \| \theta_i - \bar{\theta} \|, \]

where the first and second terms of the right hand side of (14) are the standard optimality gap of non-convex min/max problems while the third term is the consensus violation gap that characterizes the difference among the weights over the network, where $\bar{\theta} \triangleq \frac{1}{n-1} \sum_{i=1}^n \theta_i$.

Definition 2. If a point $(\{ \theta^*_i, \lambda^*_i, \forall i \})$ satisfies \[ \| G(\{ \theta^*_i, \lambda^*_i, \forall i \}) \| \leq \epsilon, \] then we call this point as the $\epsilon$-approximate first-order stationary points of (3), abbreviated as $\epsilon$-FOSP.

Remark 1. Note that points $(\{ \theta^*_i, \lambda^*_i, \forall i \})$ satisfying condition $G(\{ \theta^*_i, \lambda^*_i, \forall i \}) = 0$ is also known as “quasi-Nash equilibrium” points (Pang and Scutari 2011) or “first-order Nash equilibrium” points (Nouiehed et al. 2019). The convergence results of Safe Dec-PG are given below.

Theorem 1. Suppose Assumption 1 to Assumption 4 hold and the iterates $(\{ \theta^*_i, \lambda^*_i, \forall i \})$ are generated by Safe Dec-PG. If the total number of iterations of the algorithm is $N$ and

\[ T \sim \Omega(\log(N)), \quad \gamma^* \sim \mathcal{O}\left(\frac{1}{\sqrt{T}}\right), \quad \beta^* \sim \mathcal{O}\left(\frac{1}{\sqrt{T}}\right), \]

then we have

\[ \mathbb{E}[G^2(\{ \theta^*_i, \lambda^*_i, \forall i \})] \leq \mathcal{O}\left(\frac{\log(N)}{\sqrt{N}}\right) + \mathcal{O}(\sigma^2(T,K)) \]

where constant $\sigma^2(T,K)$ denotes the variance of PG estimation with respect to function $g(\cdot)$, and $r'$ is picked randomly from $1, \ldots, N$.

Theorem 1 says that Safe Dec-PG is able to find the solution of (1) at a rate of at least $\mathcal{O}(\log(N)/N^{1/2})$ to a neighborhood of the $\epsilon$-FOSP of this problem, where the radius of this ball is determined by the number of trajectories and length of the horizon approximation. The number of trajectories is or the longer the length is, the smaller the radius will be.

Corollary 1. Suppose Assumption 1 to Assumption 4 hold and the iterates $(\{ \theta^*_i, \lambda^*_i, \forall i \})$ are generated by Safe Dec-PG. When $T, \gamma^*, \beta^*$ satisfy (15) and $K \sim \mathcal{O}(\sqrt{N})$, then we have

\[ \mathbb{E}[G^2(\{ \theta^*_i, \lambda^*_i, \forall i \})] \leq \mathcal{O}\left(\frac{\log(N)}{\sqrt{N}}\right) \]

where the total number of iterations of the algorithm is $N$, and $r'$ is picked randomly from $1, \ldots, N$.

Note that the proposed Safe Dec-PG is not only applicable to constrained MDP problems, but also amenable to solve general stochastic non-convex concave min-max optimization problems.

Remark 2. To the best of our knowledge, our results are new in both RL and optimization communities.

- When $T$ is infinitely large, i.e., $\epsilon_f(T) = \epsilon_g(T) = 0$, Safe Dec-PG is reduced to a decentralized stochastic non-convex min-max optimization algorithm. In this regime, Safe Dec-PG also provides the state-of-the-art convergence rate to a neighborhood of FOSPs.

- When $K$ and $T$ are both infinitely large, i.e., $\epsilon_f(T) = \epsilon_g(T) = \sigma_f^2(T,K) = \sigma_g^2(T,K) = 0$, Safe Dec is reduced to a deterministic decentralized non-convex min-max algorithm. The convergence rate of Safe Dec-PG is still $\mathcal{O}(\log(N)/N^{1/2})$ but with guarantees to the $\epsilon$-FOSPs, matching the rate of HiBSA in the centralized case.

Remark 3. The number of nodes, $n$, is not shown up in the numerator of the convergence rate result, indicating that the achievable rate in (17) will not be slowed down by increasing the number of agents and the radius of the neighborhood in (16) will not be magnified as well.
Numerical Results

Problem setting To show the performance of safe decentralized RL, we test our algorithm on the environment of the Cooperative Navigation task in (Lowe et al. 2017), which is built on the popular OpenAI Gym paradigm (Brockman et al. 2016). The experiments were run on the NVIDIA Tesla V100 GPU with 32GB memory. In the first experiment, we have \( n = 5 \) agents aiming at finding their own landmarks, and all agents are connected by a well-connected graph as shown in Figure 1(a), where every agent can only exchange their parameters \( \theta \), with its neighbors through the communication channel (denoted by the green lines). Furthermore, each agent has 5 action options: stay, left, right, up, and down. We assume the states and actions of all the agents to be globally observable. The goal of the teamed agents is to find an optimal policy such that the long term discounted cumulative reward averaged over the network is maximized under a minimum number of collisions with other agents in a long term perspective.

Environment Different from the existing simulation environment, we create a new one based on the cooperative navigation task, where we set the agent and landmark as pairs and require that each agent only targets its own corresponding landmark. The rewards considered in the objective function include two parts: i) the first one is based on the distance between the location of the node to its desired landmark, which is a monotonically decreasing function of the distance, (i.e., the smaller the distance, the higher the reward will be); ii) the second one is determined by the minimum distance between two agents. If the distance between two agents is lower than a threshold, then we consider that a collision happens, and both of the agents will be penalized by a large negative reward value, i.e., \(-1\). Finally, the reward at each agent is further scaled by different positive coefficients, representing the heterogeneity, e.g., priority levels, of different agents. The rewards considered in the constraints of (3) are monotonically increasing functions of the minimum distance between two agents, i.e., the closer the two agents are, the lower the reward will be. Here, since only the minimum distance is taken into account at each node, so \( m = 1 \).

Parameters The policy at each agent is parametrized by a neural network, where there are two hidden layers with 30 neurons in the first layer and 10 neurons in the second. The states of each agent include its position and velocity. Thus, the dimension of the input layer is 20, and the output layer is 5. The discounting factor \( \gamma \) in the cumulative loss is 0.99 in all the tests, and for each episode, the length of the horizon approximation of PG is \( T = 20 \). Also, we set \( K = 10 \) Monte Carlo trials independently to compute the approximate PG at each iteration.

In this section, we only show the results of comparing Safe Dec-PG and DSGT without safety considerations in Figure 1(b) and Figure 1(c), and additional results with more problem settings, e.g., larger networks, are included in the supplemental materials. From Figure 1(b), it can be observed that the averaged network constrained rewards obtained by Safe Dec-PG are much higher than the ones achieved by DSGT and Safe Dec-PG converges faster than DSGT as well. From the statistic perspective, this long term cumulative rewards in the constraints could be interpreted as some prior knowledge accounted in MDP. From Figure 1(c), we can see that the rewards in objective function achieved by both Safe Dec and DSGT are similar, implying that the added constraints would not affect the loss of the objective rewards.

Concluding Remarks

In this work, we have proposed the first algorithm of being able to solve multi-agent CMDP problems, where the cumulative rewards in both loss function and constraints are included. By leveraging the primal-dual optimization framework, the proposed Safe Dec-PG is to maximize the averaged network long term cumulative rewards and take the safety related constraints as well. Theoretically, we provide the first convergence rate guarantees of the decentralized stochastic gradient descent ascent method to an \( \epsilon \)-FOSP of a class of non-convex min-max problems at a rate of \( O(1/\epsilon^3) \). Numerical results show that the obtained constraint rewards by Safe Dec-PG are indeed much higher than the case where the safety consideration is not incorporated without loss of both convergence rate and final objective rewards.
References

Our main contributions are regarding the theoretical results for solving a non-convex min-max optimization problem over a graph/network. The algorithm design and convergence analysis are both new. Although Safe Dec is developed in this paper for dealing with a constrained Markov decision process related problem, it can be also applied to solve other min-max optimization problems. Further, the theoretical analysis includes multiple new theorem proving techniques that would be used for performing convergence analysis for other algorithms. Therefore, this work would be beneficial for both scientists/professors who are conducting research in the area of reinforcement learning and students who are studying optimization, engineering, data science, finance, etc. We haven’t found any negative impact of this work on both ethical aspects and future societal consequences.

Preliminaries

In this section, we will provide some results that serve as the stepping stones for the subsequent analysis.

Inequalities and relations

In the proof of the main result, we will use several standard inequalities, which is given below.

1. Quadrilateral identity:

\[
\langle v_{i}^{r+1}, \lambda_{i}^{r+1} - \lambda_{i}^{r} \rangle = \frac{1}{2} (\|\lambda_{i}^{r+1} - \lambda_{i}^{r}\|^2 + \|v_{i}^{r+1}\|^2 - \|\lambda_{i}^{r} - \lambda_{i}^{r-1}\|^2)
\]  

(18)

where

\[
v_{i}^{r+1} \triangleq \lambda_{i}^{r+1} - \lambda_{i}^{r} - (\lambda_{i}^{r} - \lambda_{i}^{r-1}).
\]  

(19)

2. Young’s inequality with parameter \(\beta > 0\):

\[
\langle \theta, \theta' \rangle \leq \frac{1}{2\beta}||\theta||^2 + \frac{\beta}{2}||\theta'||^2.
\]  

(20)

Notations

Before conducting the convergence analysis, we provide the following definitions and notations that will be useful in stating the relations of the variables in the proofs.
Concatenation of individual vectors First, for notational simplicity, let $\theta^i$ and $\theta$ be concatenations of all individual ones of the network given below:

$$\theta \equiv \begin{bmatrix} \theta_1 \\ \vdots \\ \theta_n \end{bmatrix} \in \mathbb{R}^{nd}, \quad \theta^i \equiv \begin{bmatrix} \theta_{i1} \\ \vdots \\ \theta_{in} \end{bmatrix} \in \mathbb{R}^{nd}, \quad \lambda \equiv \begin{bmatrix} \lambda_1 \\ \vdots \\ \lambda_n \end{bmatrix} \in \mathbb{R}^{nm}. \quad (21)$$

Then, the updates of parameter $\theta$ and PG tracking variable $\theta^i$ can be written as

$$\theta^{i+1} = W\theta^i - \beta^r \theta^i, \quad (22a)$$
$$\theta^{r+1} = W\theta^r + \nabla_{\theta} F(\theta^{r+1}, \lambda^r) - \nabla_{\theta} F(\theta^r, \lambda^r) \quad (22b)$$

where

$$\nabla_{\theta} F(\theta^r, \lambda^r) \equiv \begin{bmatrix} \nabla_{\theta_{i1}} f_1(\theta^r_{i1}, \lambda^r_1) \\ \vdots \\ \nabla_{\theta_{in}} f_n(\theta^r_{in}, \lambda^r_n) \end{bmatrix} \in \mathbb{R}^{nd}. \quad (23)$$

Variables in consensus space Second, define the vectors in the consensus space:

$$\bar{\theta} \equiv \frac{1}{n} 1^T \theta, \quad \bar{\theta}^i \equiv \frac{1}{n} 1^T \theta^i \quad (24)$$

where $1$ denotes the all-ones vector.

Note that $\theta^0_i \equiv 0, \forall i$. Multiplying by $n^{-1} 1^T$ on both sides of (22b), we have the following relation between $\bar{\theta}^r$ and $\nabla_{\theta} f_i(\theta^r_i, \lambda^r_i)$:

$$\bar{\theta}^r = \frac{1}{n} \sum_{i=1}^{n} \nabla_{\theta} f_i(\theta^r_i, \lambda^r_i). \quad (25)$$

For simplicity, let

$$f(\bar{\theta}, \lambda) \equiv \frac{1}{n} \sum_{i=1}^{n} f_i(\theta_i, \lambda_i). \quad (26)$$

“Virtual” sequences Third, we define a virtual sequence that uses the exact PG to update the iterates:

$$\theta^{r+1} \equiv W\theta^r + \nabla_{\theta} F(\theta^{r+1}, \lambda^r) - \nabla_{\theta} F(\theta^r, \lambda^r), \quad (27)$$
$$\bar{\theta}^r \equiv \frac{1}{n} \sum_{i=1}^{n} \nabla_{\theta} f_i(\theta^r_i, \lambda^r_i). \quad (28)$$

Here $\nabla_{\theta} F(\theta^{r+1}, \lambda^r)$ represents the concatenations of all exact individual PG (i.e., $\nabla_{\theta} f_i(\theta_i, \lambda_i), \forall i$), similar to (23), where $\nabla_{\theta} f_i(\theta_i, \lambda_i) \equiv \nabla_{\theta} J_i^R(\theta_i) - \langle \nabla_{\theta} J_i^L(\theta_i), \lambda_i \rangle$. Variable $\theta^r$ denotes the weights updated if the sampling size and the length of the horizon approximate were infinitely large.

Relations between the Safe Dec sequence and the “Virtual” one Then, the averaged iterates can be expressed as:

$$\bar{\theta}^{r+1} = \bar{\theta}^r - \frac{\beta^r}{n} 1^T \bar{\theta}^r \quad (29)$$
$$\bar{\theta}^r = \frac{1}{n} \sum_{i=1}^{n} (\theta^r - 1^T \theta^r + 1^T \bar{\theta}^r) \quad (30)$$
$$\bar{\theta}^r = \frac{1}{n} 1^T \theta^r - \frac{\beta^r}{n} 1^T (\theta^r - 1^T \bar{\theta}^r), \forall r \quad (31)$$

where $\bar{\theta}^r = \frac{1}{n} \sum_{i=1}^{n} \theta^r_i$. Equation (29) implies that the stochastic version of $\theta^r$ can be interpreted as the case where $\bar{\theta}^r$ is updated in a deterministic way plus an error term denoted by $\theta^r - 1^T \bar{\theta}^r$ that shows the disagreement between $\theta^r$ and averaged $\{\theta^r_i, \forall i\}$.

Definitions and notations To better understand the forthcoming proofs, we summarize definitions of the parameters in Table 2.

Notes: we allow for the number of constraint at each node be any number $m$, so function $g_i(\theta_{i})$ is mapping from $\mathbb{R}^d$ to $\mathbb{R}^m$. Further, we define

$$F^r \equiv \{\theta^r, \ldots, \theta^{i0}, \theta^{r}, \ldots, \theta^0, \lambda^r, \ldots, \lambda^0\} \quad (32)$$

as the historical trajectories of the random variables up to the $r$th iteration.

\footnote{Note: notations $\theta$ in the supplemental material represents a different meaning as in the main text. Here, $\theta \in \mathbb{R}^{nd}$ is the concatenation of individual variables while $\theta \in \mathbb{R}^d$ in the main text denotes the parameters of the policy in the centralized setting.}

Policy Gradient Estimate

In this section, we will provide some unique features of the PG estimate in terms of both biasedness and variance, which will be useful in quantifying the convergence behavior of Safe Dec-PG. To be precise and rigorous, we introduce the following lemmas.

Lemma 1 (Biased policy gradient). Suppose that Assumption 3 and Assumption 4 hold. For any $\theta_i$ and $\lambda_i$, the bias of the corresponding policy gradients is bounded by

$$
\left\| E \left[ \nabla^{T,K}_{\theta_i} f_i(\theta, \lambda_i) - \nabla_{\theta_i} f_i(\theta_i, \lambda_i) \right] \right\| \leq G' G (1 + m \sigma_\lambda) \left( T + \frac{\gamma}{1 - \gamma} \right) \gamma^T, \forall i. \tag{33}
$$

$$
\left\| E \left[ \nabla^{T,K}_{\lambda_i} f_i(\theta, \lambda_i) - \nabla_{\lambda_i} f_i(\theta_i, \lambda_i) \right] \right\| \leq \sqrt{m G \gamma^T}, \forall i. \tag{34}
$$
Proof. Part I: for any $\theta_i \in \mathbb{R}^d$, it follows that
\begin{align}
&\| \mathbb{E}[\nabla_{\theta_i} T^K f_i(\theta_i, \lambda_i) - \nabla_{\theta_i} f_i(\theta_i, \lambda_i)] \| \\
\leq& \frac{1}{K} \mathbb{E} \left[ \sum_{t=1}^{\infty} \sum_{k=1}^K \left( \sum_{r=0}^t \nabla \log \pi(a_{t,k}^r | s_{t,k}^r; \theta_i) \right) \gamma^r R_i(s_k^t, a_k^t) \right. \\
&\left. - \sum_{t=K}^{T} \sum_{k=1}^K \left( \sum_{r=0}^t \nabla \log \pi(a_{t,k}^r | s_{t,k}^r; \theta_i) \right) \gamma^r C_i(s_k^t, a_k^t), \lambda_i \right] \right\|
\end{align}

where in (a) we first take expectation conditioned on index number $k$ and then take expectation with respect to the randomness of the $k$th sampled trajectory, (b) uses Jensen’s inequality, (c) follows from the triangle inequality, and (d) uses the bounds on the loss and constraints as well as the partial gradients in Assumption 3. We can calculate the summation as
\begin{align}
\sum_{t=1}^{\infty} t \gamma^t = \left( \frac{T}{1 - \gamma} + \frac{\gamma}{(1 - \gamma)^2} \right) \gamma^T.
\end{align}

Plugging (37) into (36) leads to
\begin{align}
\| \mathbb{E}[\nabla_{\theta_i} T^K f_i(\theta_i, \lambda_i) - \nabla_{\theta_i} f_i(\theta_i, \lambda_i)] \| \leq G'G(1 + m \sigma) \left( T + \frac{\gamma}{1 - \gamma} \right) \frac{\gamma^T}{1 - \gamma}
\end{align}
from which the first part of the proof is complete.

Part II: Similarly, we also have
\begin{align}
\| \mathbb{E}[g_i(\theta_i) - g_i(\theta_i)] \| &= \mathbb{E} \left[ \sum_{k=1}^K \gamma^r C_i(s_k^t, a_k^t) \right] \leq \frac{1}{K} \mathbb{E} \left[ \sum_{t=1}^{\infty} \gamma^r C_i(s_k^t, a_k^t) \right] \\
&\leq \sqrt{mG} \sum_{t=1}^{\infty} \gamma^r \leq \sqrt{mG} \gamma^T.
\end{align}

Note that here $C_i(\cdot, \cdot)$ is a vector function with dimension $m$.

Remark 4. Lemma 1 indicates that the upper bounds of the PG biased in both the objective function and constraints are shrinking in the order of the exponential with respect to discounted factor $\gamma$, i.e., $O(\gamma^T)$, implying that if $T \sim O(\log(N))$, then $\gamma^T \sim O(1/N)$ for a constant $N \geq 1$.

Lemma 2 (Variance of policy gradient). Suppose that Assumption 3 and Assumption 4 hold. For any $\theta_i$ and $\lambda_i$, the variance of
\begin{align}
\sum_{t=1}^{\infty} t \gamma^t = \left( \frac{T}{1 - \gamma} + \frac{\gamma}{(1 - \gamma)^2} \right) \gamma^T.
\end{align}
the corresponding policy gradients are bounded by
\[
\mathbb{E} \left[ \left\| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \nabla_{\theta_i} f_i(\theta_i, \lambda_i) \right\|^2 \right] \leq \frac{2 \gamma^2 G^2 G^2 (1 + m \sigma_\lambda)^2}{K(1 - \gamma)^4} + 2 \epsilon_f^2(T), \forall i.
\]
\[
\mathbb{E} \left[ \left\| \hat{\nabla}^{T,K}_{\lambda_i} f_i(\theta_i, \lambda_i) - \nabla_{\lambda_i} f_i(\theta_i, \lambda_i) \right\|^2 \right] \leq \frac{2 m G^2}{(1 - \gamma)^2 K} + 2 \epsilon_f^2(T), \forall i.
\]

**Proof.** **Part I:** we first decompose the error as
\[
\mathbb{E} \left[ \left\| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \nabla_{\theta_i} f_i(\theta_i, \lambda_i) \right\|^2 \right] = \mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] + \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] - \nabla_{\theta_i} f_i(\theta_i, \lambda_i) \right|^2 \right] \]
\[
\leq 2 \mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] \right|^2 \right] + 2 \left| \left| \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] - \nabla_{\theta_i} f_i(\theta_i, \lambda_i) \right|^2 \right] \]
\[
(\text{a}) \leq 2 \mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] \right|^2 \right] + 2 \epsilon_f^2(T) \]
\[
(\text{b}) \leq 2 \mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] \right|^2 \right] + 2 \epsilon_f^2(T)
\]
(40)

where in (a) we have used Young’s inequality, and in (b) we have applied Lemma 1. Further, the first term can be bounded as
\[
\mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i)] \right|^2 \right] \leq \frac{1}{K} \mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,1}_{\theta} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,1}_{\theta} f_i(\theta_i, \lambda_i)] \right|^2 \right] \right].
\]
(41)

Next, use
\[
E \left[ \left| \left| \hat{\nabla}^{T,1}_{\theta} f_i(\theta_i, \lambda_i) - E[\nabla^{T,1}_{\theta} f_i(\theta_i, \lambda_i)] \right|^2 \right] \]
\[
(\text{a}) \leq E \left[ \left| \left| \nabla^{T,1}_{\theta} f_i(\theta_i, \lambda_i) \right|^2 \right] \]
\[
(\text{b}) \leq E \left[ \sum_{t=0}^{T} \left( \sum_{i=0}^{\gamma} \nabla \log \pi(a_{t,1}^i \mid s_t^i, \theta_i) \right) \gamma^t R_i(s_t^i, a_t^i) \right]
\[
- \sum_{t=0}^{T} \left( \sum_{i=0}^{\gamma} \nabla \log \pi(a_{t,1}^i \mid s_t^i, \theta_i) \right) \gamma^t C_i(s_t^i, a_t^i, \lambda_i) \right] \]
\[
\leq \frac{\gamma^2 G^2 G^2 (1 + m \sigma_\lambda)^2}{(1 - \gamma)^4}
\]
(42)

where (a) is true due to \( \text{Var}(X) \leq \mathbb{E}X^2 \), (b) employs the bounds on the loss, constraints and dual variable as well as the partial gradients in Assumption 3.

Therefore, we have
\[
\mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\theta} f_i(\theta_i, \lambda_i) - \nabla_{\theta_i} f_i(\theta_i, \lambda_i) \right|^2 \right] \leq \frac{2 \gamma^2 G^2 G^2 (1 + m \sigma_\lambda)^2}{K(1 - \gamma)^4} + 2 \epsilon_f^2(T).
\]
(43)

**Part II:** Similarly, we have
\[
\mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\lambda_i} f_i(\theta_i, \lambda_i) - \nabla_{\lambda_i} f_i(\theta_i, \lambda_i) \right|^2 \right] \]
\[
=\mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,K}_{\lambda_i} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,K}_{\lambda_i} f_i(\theta_i, \lambda_i)] + \mathbb{E}[\hat{\nabla}^{T,K}_{\lambda_i} f_i(\theta_i, \lambda_i)] - \nabla_{\lambda_i} f_i(\theta_i, \lambda_i) \right|^2 \right] \]
\[
(\text{a}) \leq \frac{2}{K} \mathbb{E} \left[ \left| \left| \hat{\nabla}^{T,1}_{\lambda_i} f_i(\theta_i, \lambda_i) - \mathbb{E}[\hat{\nabla}^{T,1}_{\lambda_i} f_i(\theta_i, \lambda_i)] \right|^2 \right] + 2 \epsilon_f^2(T)
\]
(45)
where \((a)\) follows from Lemma 1. And the first term in (45) can be upper bounded further by

\[
\mathbb{E} \left[ \left\| \nabla \theta^T f_i(\theta_i, \lambda_i) - \mathbb{E}[\nabla \theta^T f_i(\theta_i, \lambda_i)] \right\|^2 \right] 
\leq \mathbb{E} \left[ (\tilde{f}_i^T)^T f_i(\theta_i) \right]^2 
\leq \mathbb{E} \left[ \sum_{t=0}^{T} \gamma^t C_i(s_t', a_t') \right]^2 
\leq mG^2 \left\| \sum_{t=1}^{T} \gamma^t \right\|^2 
\leq \frac{mG^2}{(1 - \gamma)^2}. \tag{46}
\]

Therefore, we have

\[
\mathbb{E} \left[ \left\| \nabla \theta^T f_i(\theta_i, \lambda_i) - \nabla \lambda_i f_i(\theta_i, \lambda_i) \right\|^2 \right] 
\leq \frac{2mG^2}{(1 - \gamma)^2 K} + 2\epsilon^2_g(T). \tag{47}
\]

**Remark 5.** It is obvious that the both two terms in \(\sigma_f^2(T, K)\) and \(\sigma_g^2(T, K)\) are shrinking with respect to either \(K\) or \(T\), i.e., \(O(1/K)\) or \(O(\gamma^T)\) (where \(\gamma < 1\)). Since the decreasing rate of \(O(1/K)\) is lower than \(O(\gamma^T)\) for \(O(T) \sim O(K)\), we conclude that \(\sigma_f^2(T, K)\) and \(\sigma_g^2(T, K)\) will be shrunk with respect to \(K\) in an order of \(O(1/K)\).

**Sufficient Descent of Minimization**

In this section, we will focus on the minimization and consensus part of Safe Dec.

**Bounded variance of tracking variable**

By defining the virtual sequence \(\tilde{\theta}^r\), we can have the following upper bound of the difference between \(\tilde{\theta}^r\) and \(\theta^r\).

**Lemma 3.** *(Bounded Variance)* If the iterates \(\{\tilde{\theta}^r, \forall r\}\) are generated by Safe Dec-PG, under Assumption 1 to Assumption 4, we have

\[
\mathbb{E} \left\| \theta^r - \tilde{\theta}^r \right\|^2 \leq nK\sigma_f^2(T, K), \tag{48}
\]

where

\[
\kappa \triangleq (1 + 2/(1 - \eta))^2. \tag{49}
\]

**Proof.** From (22b) and (27), we have

\[
\|\tilde{\theta}^{r+1} - \theta^{r+1}\| \leq \mathbb{E} \left[ \nabla_{\theta} T, K F(\theta^{r+1}, \lambda^r) - \nabla_{\theta} F(\theta^{r+1}, \lambda^r) \right]
\leq \mathbb{E} \left[ \tilde{\nabla}_{\theta} T, K F(\theta^r, \lambda^{r-1}) - \nabla_{\theta} F(\theta^r, \lambda^{r-1}) \right] \tag{50}
\]

where in (b) we have used inequality \((a)\) recursively.

Taking expectation on the random trajectories at the \(r + 1\)th iteration on both sides of (51) conditioned on \(\mathcal{F}^r\), we have

\[
\mathbb{E} \left\| \tilde{\theta}^{r+1} - \theta^{r+1} \right\| \leq \mathbb{E} \left\| (\mathbb{W} - I) \left( \tilde{\nabla}_{\theta} T, K F(\theta^r, \lambda^{r-1}) - \nabla_{\theta} F(\theta^r, \lambda^{r-1}) \right) \right\| \tag{52}
\]

where \((a)\) follows from Lemma 2.

By leveraging this fact, we take expectation over \(\mathcal{F}^r\) on both sides of (52) conditioned on \(\mathcal{F}^{r-1}\) for all \(r\) recursively, and have

\[
\mathbb{E} \left\| \tilde{\theta}^{r+1} - \theta^{r+1} \right\| \leq \mathbb{E} \left[ (\mathbb{W} - I) \left( \tilde{\nabla}_{\theta} T, K F(\theta^1, \lambda^0) - \nabla_{\theta} F(\theta^1, \lambda^0) \right) \right] \tag{53}
\]

where in \((a)\) we have used \(\|\mathbb{W}(\mathbb{W} - I)\| \leq \|\lambda_{\text{max}}(\mathbb{W})\| \|\mathbb{W} - I\|\) since \((\mathbb{W} - I)1 = 0\) (i.e., \(\mathbb{W} - I\) lies in the null space of \(1\)) and \(\|\lambda_{\text{max}}(\mathbb{W})\| = \eta < 1\) and \(\|\mathbb{W} - I\| \leq 2\).
Descent of policy gradient

**Lemma 4.** (Descent Lemma regarding minimization) Under Assumption 1, Assumption 3, and Assumption 4, suppose that the iterates \( \{ \theta_t^r, \forall i \} \) are generated by Safe Dec-PG. Then, there exists a constant \( \varphi \in (0, 1) \) such that

\[
\mathbb{E} \left[ f(\theta^{r+1}, \lambda^r) \right] \leq \mathbb{E} \left[ f(\theta^r, \lambda^r) \right] + \frac{\beta^r L^2}{2\varphi} \mathbb{E} \left\| \theta^r - 1\theta^r \right\|^2 - \left( \beta^r - \left( \frac{\beta^r \varphi}{2} + (\beta^r)^2 L \right) \right) \mathbb{E} \left\| \theta^r \right\|^2

+ \frac{(\beta^r)^2 L \sigma_r^2(T, K)}{n} + \epsilon_f(T) \mathbb{E} \left\| \nabla f(\theta^r, \lambda^r) \right\|.
\]  

(54)

**Proof.** Under the gradient Lipschitz continuity of the objective function with respect to \( \theta \), we have

\[
f(\theta^{r+1}, \lambda^r) \leq f(\theta^r, \lambda^r) + \langle \nabla f(\theta^r, \lambda^r), \theta^{r+1} - \theta^r \rangle + \frac{L}{2} \left\| \theta^{r+1} - \theta^r \right\|^2
\]

(29)

\[
eq f(\theta^r, \lambda^r) - \beta^r \langle \nabla f(\theta^r, \lambda^r), \theta^r \rangle - \beta^r \langle \nabla f(\theta^r, \lambda^r), \frac{1}{n} \mathbb{1}^T (\theta^r - 1\theta^r) \rangle

+ \left( \beta^r \right)^2 \mathbb{E} \left\| \theta^r \right\|^2 + \frac{(\beta^r)^2 L \sigma_r^2(T, K)}{n} + \epsilon_f(T) \mathbb{E} \left\| \nabla f(\theta^r, \lambda^r) \right\|
\]

(55)

where (a) follows from Young’s inequality with parameter \( \varphi \) (that will be tuned later), and in the last inequality we have used the fact that \( \mathbb{1}^T (\theta^r - 1\theta^r) = 0 \).

Applying Lemma 1, we can get the upper bound of \( \langle \nabla f(\theta^r, \lambda^r), \frac{1}{n} \mathbb{1}^T (\theta^r - 1\theta^r) \rangle \) in expectation as the following,

\[
\mathbb{E}_{\mathcal{F}^{r+1}} [\langle \nabla f(\theta^r, \lambda^r), \frac{1}{n} \mathbb{1}^T (\theta^r - 1\theta^r) \rangle] \leq \left\| \nabla f(\theta^r, \lambda^r) \right\| \epsilon_f(T),
\]

(56)

where in (a) we have used (25) and (28).

Next, taking expectation on both sides of (55) yields

\[
\mathbb{E} \left[ f(\theta^{r+1}, \lambda^r) \right] \leq \mathbb{E} \left[ f(\theta^r, \lambda^r) \right] + \frac{\beta^r \varphi}{2} \mathbb{E} \left\| \nabla f(\theta^r, \lambda^r) \right\|^2 + \frac{(\beta^r)^2 L \sigma_r^2}{2n} \mathbb{E} \left\| \theta^r \right\|^2 + \left( \beta^r - \left( \frac{\beta^r \varphi}{2} + (\beta^r)^2 L \right) \right) \mathbb{E} \left\| \theta^r \right\|^2

+ \frac{(\beta^r)^2 L \sigma_r^2(T, K)}{n} + \epsilon_f(T) \mathbb{E} \left\| \nabla f(\theta^r, \lambda^r) \right\|
\]

(57)

where (a) is true because \( \mathbb{E} \left\| \theta^r - 1\theta^r \right\|^2 \leq \sigma_r^2(T, K)/n \), and in (b) we use \( \mathbb{E} \left\| \nabla f(\theta^r, \lambda^r) \right\| \leq \frac{L^2}{n} \mathbb{E} \left\| \theta^r - 1\theta^r \right\|^2 \) by applying Assumption 1 and (28).

**Network contraction**

Second, after each step of communication or consensus procedure over the graph, we are able to obtain the following contraction property of the consensus violation.

**Lemma 5.** (Consensus contraction) Under Assumption 1 to Assumption 4, we have the following contraction property of the iterates generated by Safe Dec-PG:

\[
\frac{1}{n} \mathbb{E} \left\| \theta^{r+1} - 1\theta^r \right\|^2 \leq \frac{1}{n} (1 + \nu) \eta^2 \mathbb{E} \left\| \theta^r - 1\theta^r \right\|^2 + \frac{3}{n} \left( 1 + \frac{1}{\nu} \right) \left( \beta^r \right)^2 \mathbb{E} \left\| \theta^r - 1\theta^r \right\|^2

+ \frac{(\beta^r)^2 \kappa \sigma_r^2(T, K)}{n},
\]

(58)
and

\[
\frac{1}{n} \mathbb{E} \| \theta^{r+1} - \bar{\theta}^{r+1} \|^2 \leq 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right)^2 \mathbb{E} \| \bar{\theta}^r \|^2 \\
+ \frac{1}{n} \left( L^2 \eta^2 (1 + \nu) \left( 1 + \frac{1}{\nu} \right) + 4L^2 \left( 1 + \frac{1}{\nu} \right)^2 \right) \mathbb{E} \| \theta^r - \bar{\theta}^r \|^2 \\
+ \frac{1}{n} \left( (1 + \nu) \eta^2 + 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right)^2 \right) \mathbb{E} \| \theta^r - \bar{\theta}^r \|^2 \\
+ 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right)^2 \kappa \sigma_f^2(T, K) 
\]  

(59)

where \( \nu \) is some constant such that \((1 + \nu)\eta^2 < 1\), and \( \kappa \) is a constant defined in (3).

**Proof.**  
**Part I:** First, using the assumption on \( W \), we can obtain the contraction property of the iterates disagreement of the network, i.e.,

\[
\| W\theta^r - 1\bar{\theta}^r \| = \| W(\theta^r - 1\bar{\theta}^r) \| \leq \eta \| \theta^r - 1\bar{\theta}^r \| 
\]

(60)

where \((a)\) is true due to the fact that \( 1^T (\theta^r - 1\bar{\theta}^r) = 0 \), i.e., \( \theta^r - 1\bar{\theta}^r \in \text{col}(W) \) and \( |\lambda_{\text{max}}(W)| = \eta < 1 \).

Then, applying the definition of (22a) and Young’s inequality, we have

\[
\| \theta^{r+1} - 1\bar{\theta}^{r+1} \|^2 \\
= \| W\theta^r - \beta^r\bar{\theta}^r - 1(\bar{\theta}^r - \beta^r\bar{\theta}^r) \|^2 \\
\leq (1 + \nu) \| W\theta^r - 1\bar{\theta}^r \|^2 + \left( 1 + \frac{1}{\nu} \right) (\beta^r)^2 \| \theta^r - 1\bar{\theta}^r \|^2 \\
\leq (1 + \nu) \eta^2 \| \theta^r - 1\bar{\theta}^r \|^2 + 3 \left( 1 + \frac{1}{\nu} \right) (\beta^r)^2 \| \theta^r - \bar{\theta}^r \|^2 \\
+ 3 \left( 1 + \frac{1}{\nu} \right) (\beta^r)^2 \| \theta^r - 1\bar{\theta}^r \|^2 + 3 \left( 1 + \frac{1}{\nu} \right) (\beta^r)^2 \| 1\bar{\theta}^r - 1\bar{\theta}^r \|^2 
\]

(61)

in which \( \nu \in (0, 1) \) is some constant parameter that will be chosen later. After taking exception on the both sides of (61) we have the desired results by applying Lemma 3.

**Part II:** Recall that

\[
\nabla_{\theta} F(\theta^r, \lambda^r) \triangleq \begin{bmatrix}
\nabla_{\theta_1} f_1(\theta_1^r, \lambda_1^r) \\
\vdots \\
\nabla_{\theta_n} f_n(\theta_n^r, \lambda_n^r)
\end{bmatrix}.
\]

(62)

Similarly, applying the definition of \( \theta^r \) shown in (27), we have

\[
\| \theta^{r+1} - 1\bar{\theta}^{r+1} \|^2 \\
= \| W\theta^r + \nabla_{\theta} F(\theta^{r+1}, \lambda^r) - \nabla_{\theta} F(\theta^r, \lambda^r) - \frac{1}{n} 11^T( W\theta^r + \nabla_{\theta} F(\theta^{r+1}, \lambda^r) - \nabla_{\theta} F(\theta^r, \lambda^r)) \|^2 \\
\leq (1 + \nu) \eta^2 \| \theta^r - 1\bar{\theta}^r \|^2 + \left( 1 + \frac{1}{\nu} \right) \| \nabla_{\theta} F(\theta^{r+1}, \lambda^r) - \nabla_{\theta} F(\theta^r, \lambda^r) \|^2. 
\]

(63)
Next, combining the following fact
\[
\| \nabla_\theta F(\theta^{r+1}, \lambda^r) - \nabla_\theta F(\theta^r, \lambda^r) \|^2 \\
\leq L^2 \| \theta^{r+1} - \theta^r \|^2 \\
\overset{(2a)}{=} \| W \theta^r - \theta^r - \beta^r \theta^r \|^2 \\
= L^2 \| W (\theta^r - 1\bar{\theta}^r) + 1\bar{\theta}^r - \theta^r - \beta^r \theta^r \|^2 \\
\leq L^2 \eta^2 (1 + \nu) \| \theta^r - 1\bar{\theta}^r \|^2 + L^2 \left( 1 + \frac{1}{\nu} \right) \| 1\bar{\theta}^r - \theta^r - \beta^r \theta^r \|^2 \\
\leq L^2 \eta^2 (1 + \nu) \| \theta^r - 1\bar{\theta}^r \|^2 + 4L^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r - 1\bar{\theta}^r \|^2 + \frac{4L^2 (\beta^r)^2}{\eta^2} \left( 1 + \frac{1}{\nu} \right) \| \theta^r - \theta^r \|^2 \\
+ 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r - 1\bar{\theta}^r \|^2 + 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r - \theta^r \|^2, \\
\]
we have
\[
\| \theta^{r+1} - 1\bar{\theta}^{r+1} \|^2 \leq \left( (1 + \nu) \eta^2 + 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \right) \| \theta^r - 1\bar{\theta}^r \|^2 \\
+ \left( L^2 \eta^2 (1 + \nu) \left( 1 + \frac{1}{\nu} \right) + 4L^2 \left( 1 + \frac{1}{\nu} \right) \right) \| \theta^r - 1\bar{\theta}^r \|^2 \\
+ 4nL^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r \|^2 + 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r - \theta^r \|^2. \\
(64) \\
\]
Taking expectation on the both sides of (64) and applying Lemma 3 asserts that
\[
E \| \theta^{r+1} - 1\bar{\theta}^{r+1} \|^2 \leq \left( (1 + \nu) \eta^2 + 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \right) E \| \theta^r - 1\bar{\theta}^r \|^2 \\
+ \left( L^2 \eta^2 (1 + \nu) \left( 1 + \frac{1}{\nu} \right) + 4L^2 \left( 1 + \frac{1}{\nu} \right) \right) E \| \theta^r - 1\bar{\theta}^r \|^2 \\
+ 4nL^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r \|^2 + 4L^2 (\beta^r)^2 \left( 1 + \frac{1}{\nu} \right) \| \theta^r - \theta^r \|^2 n\kappa \sigma^2(T, K), \\
(65) \\
\]
which completes the proof.

\[\square\]

**Ascent of Maximization**

After quantifying the descent of the minimization and consensus steps that can provide, we will measure the ascent of maximization that might incur.

To begin with, we provide a preliminary lemma that indicates the upper bound of the inner product between \( \hat{g}_i(\theta^{r+1}_i) - g_i(\theta^{r+1}_i) \) and \( \lambda^{r+1}_i - \lambda_i^r \) in expectation.

**Preliminary lemma**

**Lemma 6.** Under Assumption 3 and Assumption 4, suppose that the iterates \( \{ \theta^r, \lambda^r \} \) are generated by Safe Dec-PG. Then, we have
\[
E \langle \hat{g}_i(\theta^{r+1}_i) - g_i(\theta^{r+1}_i), \lambda^{r+1}_i - \lambda_i^r \rangle \leq \rho \sigma^2(T, K) + 2\sigma \lambda \sigma(T), \forall i. \\
(66) \\
\]

**Proof.** First, let us define
\[
\tilde{\lambda}_i^r = \mathcal{P}_{\Lambda} \left((1 - \rho \gamma^r) \lambda_i^r + \rho g_i(\theta^{r+1}_i)\right), \\
(67) \\
\]
where \( g_i(\theta^{r+1}_i) = c_i - J_i^C(\theta^{r+1}_i) \).

Then, we have
\[
\langle \hat{g}_i(\theta^{r+1}_i) - g_i(\theta^{r+1}_i), \lambda^{r+1}_i - \lambda_i^r \rangle \\
= \langle \hat{g}_i(\theta^{r+1}_i) - g_i(\theta^{r+1}_i), \lambda^{r+1}_i - \lambda_i^r - (\lambda_i^{r+1} - \lambda_i^r) \rangle \\
+ \langle \hat{g}_i(\theta^{r+1}_i) - g_i(\theta^{r+1}_i), \lambda_i^{r+1} - \lambda_i^r \rangle. \\
(68) \\
\]
Taking expectation over $\mathcal{F}^{r+1}$ conditioned on $\mathcal{F}^r$, we have
\[ \mathbb{E}\left( \tilde{g}_i(\theta_i^{r+1}) - g_i(\theta_i^{r+1}), \tilde{\lambda}_i^{r+1} - \lambda_i^r \right) \overset{(a)}{=} 2\sigma \epsilon_g(T), \] (69)
where in (a) we have used Assumption 4 and Lemma 1 or (39).

Plugging (69) in (68) with being taken expectation, we have
\[
\begin{align*}
\mathbb{E}\left[ g_i(\theta_i^{r+1}) - g_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right] \\
\overset{(a)}{=} \mathbb{E} \left[ \frac{\rho}{2} \left( \tilde{g}_i(\theta_i^{r+1}) - g_i(\theta_i^r) \right)^2 + \frac{1}{2\rho} \| \lambda_i^{r+1} - \lambda_i^r \|^2 \right] \\
\overset{(b)}{\leq} \rho \sigma_g^2(T, K) + 2\sigma \epsilon_g(T),
\end{align*}
\] (70)
(71)

where (a) follows from Young’s inequality, and the inequality in (b) is true due to non-expansiveness of the projection operator, i.e.,
\[ \| P_\lambda (1 - \rho \gamma^r) \lambda_i^r + \rho g_i(\theta_i^{r+1}) - P_\lambda (1 - \rho \gamma^r) \lambda_i^r \| \leq \rho \| g_i(\theta_i^{r+1}) - \tilde{g}_i(\theta_i^{r+1}) \|. \] (72)

\[\square\]

**Balance between descent and ascent**

To proceed, let
\[ l_i(\theta_i^r, \lambda_i^r) \triangleq \langle g_i(\theta_i^r), \lambda_i^r \rangle, \forall i. \] (73)

In the following, we will show the ascent of the loss function when the dual variable $\lambda$ is updated.

**Lemma 7.** (Ascent Lemma regarding maximization). Under Assumption 1 to Assumption 4, suppose that iterates $\{\theta_i^r, \theta_i^r, \lambda_i^r, \forall r, i\}$ are generated by Safe Dec-PG. Then, we have
\[
\frac{1}{n} \sum_{i=1}^n \mathbb{E}[l_i(\theta_i^{r+1}, \lambda_i^{r+1}) - l_i(\theta_i^r, \lambda_i^r)] \\
\leq \frac{1}{2\rho n} \mathbb{E}[\| \lambda_i^r - \lambda_i^{r+1} \|^2 + \rho L^2 \mathbb{E}[\| \theta_i^{r+1} - \theta_i^r \|^2] - \left( \frac{\gamma}{2} - \frac{1}{\rho} \right) \mathbb{E}[\| \lambda_i^{r+1} - \lambda_i^r \|^2] \\
+ \frac{\gamma}{2n} \mathbb{E}[\| \lambda_i^r \|^2] + \frac{\gamma}{2} \left( \frac{\gamma}{2} - \frac{1}{\rho} \right) \mathbb{E}[\| \lambda_i^{r+1} - \lambda_i^r \|^2] + \frac{\rho}{n} \sigma_g^3(T, K) + 4\epsilon_g(T)\sigma. \] (74)

**Proof.** Let $\tilde{f}_i(\theta_i^{r+1}, \lambda_i^{r+1}) \triangleq \langle g_i(\theta_i^{r+1}), \lambda_i^{r+1} \rangle - \mathbb{I}(\lambda_i^{r+1})$ and $\xi_i^r$ denote the subgradient of $\mathbb{I}(\lambda_i^r)$, where $\mathbb{I}(\cdot)$ denotes the indicator function. Due to the fact that set $\Lambda$ is convex, we know that the function $\tilde{f}_i(\theta_i^{r+1}, \lambda_i^r)$ is concave with respect to $\lambda_i^r$. Thus, we have
\[
\begin{align*}
\tilde{f}_i(\theta_i^{r+1}, \lambda_i^{r+1}) &- \tilde{f}_i(\theta_i^r, \lambda_i^r) \\
&= \langle g_i(\theta_i^{r+1}), \lambda_i^{r+1} - \lambda_i^r \rangle - \langle \xi_i^r, \lambda_i^{r+1} - \lambda_i^r \rangle \\
&= \langle g_i(\theta_i^{r+1}) - g_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \rangle + \langle g_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \rangle \\
&- \langle \xi_i^{r+1}, \lambda_i^{r+1} - \lambda_i^r \rangle - \langle \xi_i^r - \xi_i^{r+1}, \lambda_i^{r+1} - \lambda_i^r \rangle \\
\overset{(a)}{=} & \frac{1}{\rho} \| \lambda_i^{r+1} - \lambda_i^r \|^2 + \gamma \langle \lambda_i^{r+1} - \lambda_i^r, \lambda_i^{r+1} - \lambda_i^r \rangle + \langle \xi_i^{r+1} - \xi_i^r, \lambda_i^{r+1} - \lambda_i^r \rangle \\
\overset{(b)}{=} & \frac{1}{\rho} \| \lambda_i^{r+1} - \lambda_i^r \|^2 + \gamma \| \lambda_i^{r+1} - \lambda_i^r \|^2 + \langle \xi_i^{r+1} - \xi_i^r, \lambda_i^{r+1} - \lambda_i^r \rangle \\
\overset{(c)}{=} & \frac{1}{\rho} \| \lambda_i^r - \lambda_i^{r-1} \|^2 + \frac{\rho L^2}{2} \| \theta_i^{r+1} - \theta_i^r \|^2 - \left( \frac{\gamma}{2} - \frac{1}{\rho} \right) \| \lambda_i^{r+1} - \lambda_i^r \|^2 \\
&+ \frac{\gamma}{2} \| \lambda_i^r \|^2 - \frac{\gamma}{2} \| \lambda_i^{r+1} - \lambda_i^r \|^2 + \frac{\gamma}{2} \| \lambda_i^{r+1} \|^2 \\
&+ \langle \tilde{g}_i(\theta_i^{r+1}) - g_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \rangle + \langle g_i(\theta_i^r) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \rangle,
\end{align*}
\] (75)
where in (a) we use the optimality condition of (12), i.e.,
\[ \xi_i^{r+1} - \tilde{g}_i(\theta_i^{r+1}) + \frac{1}{\rho} (\lambda_i^{r+1} - \lambda_i^r) + \gamma \lambda_i^{r+1} = 0 \] (76)
and in (b) we use (76) again and get
\[
\langle \xi_t^{r+1} - \xi_t^r, \lambda_t^{r+1} - \lambda_t^r \rangle = \langle \hat{g}_i(\theta_t^{r+1}) - \hat{g}_i(\theta_t^r), \lambda_t^{r+1} - \lambda_t^r \rangle - \frac{1}{\rho} \langle \nu_t^{r+1}, \lambda_t^{r+1} - \lambda_t^r \rangle - \langle \gamma^r \lambda_t^{r+1} - \gamma^{r-1} \lambda_t^r, \lambda_t^{r+1} - \lambda_t^r \rangle ;
\] (77)
and (c) is true because i) after applying the quadrilateral identity and Lipschitz continuity of function \( g(\cdot) \), and thus we can have
\[
\langle \hat{g}_i(\theta_t^{r+1}) - \hat{g}_i(\theta_t^r), \lambda_t^{r+1} - \lambda_t^r \rangle = \langle \hat{g}_i(\theta_t^{r+1}) - g_i(\theta_t^{r+1}) + g_i(\theta_t^{r+1}) - g_i(\theta_t^r), \lambda_t^{r+1} - \lambda_t^r \rangle \\
\leq \frac{\rho L^2}{2} \| \theta_t^{r+1} - \theta_t^r \|^2 + \frac{1}{2\rho} \| \lambda_t^{r+1} - \lambda_t^r \|^2 + \langle \hat{g}_i(\theta_t^{r+1}) - g_i(\theta_t^{r+1}), \lambda_t^{r+1} - \lambda_t^r \rangle \\
+ \langle g_i(\theta_t^r) - \hat{g}_i(\theta_t^r), \lambda_t^{r+1} - \lambda_t^r \rangle ;
\] (78)
and also ii) the following equality
\[
\gamma^{-1} \langle \lambda_t^r, \lambda_t^{r+1} - \lambda_t^r \rangle = \frac{\gamma^{-1}}{2} (\| \lambda_t^{r+1} \|^2 - \| \lambda_t^r \|^2 - \| \lambda_t^{r+1} - \lambda_t^r \|^2) \\
= \frac{\gamma^{-1}}{2} \| \lambda_t^{r+1} \|^2 - \frac{\gamma^{-1}}{2} \| \lambda_t^r \|^2 - \frac{\gamma^{-1}}{2} \| \lambda_t^{r+1} - \lambda_t^r \|^2 + \frac{\gamma^{-1} - \gamma}{2} \| \lambda_t^{r+1} \|^2 .
\] (79)
Note that the variable \( \lambda_t^r \) is projected into the feasible set at each iteration, so we have \( \hat{f}_i(\theta_t^{r+1}, \lambda_t^{r+1}) = l(\theta_t^{r+1}, \lambda_t^{r+1}) \). Taking expectation on both sides of (75) and summing up over all the nodes, we have
\[
\sum_{i=1}^n \mathbb{E} [l_i(\theta_t^{r+1}, \lambda_t^{r+1}) - l_i(\theta_t^r, \lambda_t^r)] \\
= \mathbb{E} [\| \lambda_t - \lambda_t^{-1} \|^2 + \frac{\rho L^2}{2} \| \theta_t^{r+1} - \theta_t^r \|^2 - \left( \frac{\gamma^{-1}}{2} - \frac{1}{\rho} \right) \| \lambda_t^{r+1} - \lambda_t^r \|^2] \\
+ \frac{\gamma}{2} \mathbb{E} [\| \lambda_t^{r+1} \|^2 - \| \lambda_t^r \|^2] + \frac{\gamma^{-1} - \gamma}{2} \mathbb{E} [\| \lambda_t^{r+1} \|^2 + \rho \sigma_g^2(T, K) + 4n \epsilon_g(T) \sigma] .
\] (80)
where in (a) we have applied Lemma 6 and also the following inequality:
\[
\mathbb{E} [g_i(\theta_t^r) - \hat{g}_i(\theta_t^r), \lambda_t^{r+1} - \lambda_t^r] \leq \mathbb{E} [g_i(\theta_t^r) - \hat{g}_i(\theta_t^r)] \| 2 \sigma \leq 2 \sigma_g(T) \sigma.
\] (81)
where (i) is true because there are two steps of expectations being taken: 1) we take expectation on \( \mathcal{F}_t^{r+1} \) conditioned on \( \mathcal{F}_r \); 2) we take expectation on the randomness of the PG estimate in the constraints conditioned on \( \mathcal{F}_t^{r+1} \) and we have used Assumption 3, and (ii) follows from Lemma 2. Then, the proof is complete.

**Recursion of dual variables**

**Lemma 8.** Under Assumption 1–Assumption 4, suppose that the sequence \( \gamma^r \) is decreasing and iterates \( \{\theta_t^r, \theta_t^r, \lambda_t^r, \forall r, i\} \) are generated by Safe Dec-PG. Then, we have
\[
Q^{r+1} \leq Q^r + \frac{2}{\rho m} \left( \frac{1}{\gamma^r} - \frac{1}{\gamma^{r-1}} \right) \mathbb{E} [\| \lambda_t - \lambda_t^{r-1} \|^2 + \frac{2}{\rho m} \left( \frac{\gamma^{r-2}}{\gamma^{r-1}} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E} [\| \lambda_t \|^2] \\
- \frac{2}{\rho m} \mathbb{E} [\| \lambda_t^{r-1} \|^2 - \| \lambda_t^r \|^2] + \frac{2 L^2}{\rho m (\gamma^r)^2} \mathbb{E} [\| \theta_t^{r+1} - \theta_t^r \|^2] + \frac{4}{\rho m \gamma^r} (\rho \sigma_g^2(T, K) + 4n \epsilon_g(T) \sigma) ,
\] (82)
where
\[
Q^r \triangleq \frac{2}{\rho m \gamma^{r-1}} \mathbb{E} [\| \lambda_t - \lambda_t^{r-1} \|^2 - \frac{2}{\rho m} \left( \frac{\gamma^{r-2}}{\gamma^{r-1}} - 1 \right) \mathbb{E} [\| \lambda_t \|^2] \geq 0 .
\] (83)

**Proof.** From the optimality condition of the \( \lambda_t \)-subproblem at the \( r + 1 \)th iteration, we have
\[
- \langle \hat{g}_i(\theta_t^{r+1}) - \frac{1}{\rho} (\lambda_t^{r+1} - \lambda_t^r) - \gamma^r \lambda_t^{r+1}, \lambda_t^{r+1} - \lambda_t^r \rangle \leq 0 , \quad \forall \lambda_t^r \in \Lambda_t, \forall i .
\] (84)
Similarly, from the optimality condition of the \( \lambda_i \)-subproblem at the \( r \)th iteration, we have
\[
-\left\langle \tilde{g}_i(\theta_i^r) - \frac{1}{\rho}(\lambda_i^r - \lambda_i^{r-1}) - \gamma^{-1}\lambda_i^r, \lambda_i - \lambda_i^r \right\rangle \geq 0, \ \forall \lambda_i \in \Lambda, \forall i. \tag{85}
\]
Plugging in \( \lambda_i = \lambda_i^r \) in (84) and \( \lambda_i = \lambda_i^{r+1} \) in (85) and combining them together, we have
\[
\frac{1}{\rho} \left( \nu_i^{r+1}, \lambda_i^{r+1} - \lambda_i^r \right) + \left\langle \gamma \lambda_i^{r+1} - \gamma^{-1}\lambda_i^r, \lambda_i^{r+1} - \lambda_i^r \right\rangle \leq \left\langle \tilde{g}_i(\theta_i^{r+1}) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle, \ \forall i. \tag{86}
\]
First, note that we have the following relations
\[
\left\langle \gamma \lambda_i^{r+1} - \gamma^{-1}\lambda_i^r, \lambda_i^{r+1} - \lambda_i^r \right\rangle
= \left\langle \gamma \lambda_i^{r+1} - \gamma\lambda_i^r, \lambda_i^{r+1} - \lambda_i^r \right\rangle + \left\langle \gamma^{-1}\lambda_i^r, \lambda_i^{r+1} - \lambda_i^r \right\rangle
= \gamma^r ||\lambda_i^{r+1} - \lambda_i^r||^2 + \gamma^{-1} \left( ||\lambda_i^{r+1}||^2 - ||\lambda_i^r||^2 - ||\lambda_i^{r+1} - \lambda_i^r||^2 \right)
= \frac{\gamma^r + \gamma^{-1}}{2} ||\lambda_i^{r+1} - \lambda_i^r||^2 - \frac{\gamma^r - \gamma^{-1}}{2} \left( ||\lambda_i^{r+1}||^2 - ||\lambda_i^r||^2 \right). \tag{87}
\]
Second, substituting (87) into (86) and using (18), gives rise to
\[
\frac{1}{2\rho} ||\lambda_i^{r+1} - \lambda_i^r||^2 - \frac{\gamma^r - \gamma^{-1}}{2} ||\lambda_i^{r+1}||^2
\leq \frac{1}{2\rho} ||\lambda_i^r - \lambda_i^{r-1}||^2 - \frac{1}{2\rho} ||\nu_i^{r+1}||^2 - \frac{\gamma^r - \gamma^{-1}}{2} ||\lambda_i^r||^2 - \frac{\gamma^r + \gamma^{-1}}{2} ||\lambda_i^{r+1} - \lambda_i^r||^2
\]
\[
+ \left\langle \tilde{g}_i(\theta_i^{r+1}) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle
\leq (a) \frac{1}{2\rho} ||\lambda_i^r - \lambda_i^{r-1}||^2 - \frac{\gamma^r - \gamma^{-1}}{2} ||\lambda_i^r||^2 - \gamma^r ||\lambda_i^{r+1} - \lambda_i^r||^2 + \gamma^{-1} ||\lambda_i^{r+1}||^2 + \left\langle \tilde{g}_i(\theta_i^{r+1}) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle
\]
\[
\leq (b) \frac{1}{2\rho} ||\lambda_i^r - \lambda_i^{r-1}||^2 - \frac{\gamma^r - \gamma^{-1}}{2} ||\lambda_i^r||^2 - \gamma^r ||\lambda_i^{r+1} - \lambda_i^r||^2 + \frac{L^2}{2\gamma^r} ||\theta_i^{r+1} - \theta_i^r||^2
\]
\[
+ \frac{\gamma^r}{2} ||\lambda_i^{r+1} - \lambda_i^r||^2 + \left\langle \tilde{g}_i(\theta_i^{r+1}) - g_i(\theta_i^{r+1}), \lambda_i^{r+1} - \lambda_i^r \right\rangle + \left\langle \tilde{g}_i(\theta_i^r) - g_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle, \tag{88}
\]
where (a) is true because \( 0 < \gamma^r < \gamma^{-1} \), and in (b) we have used Young’s inequality, Lipschitz continuity, i.e.,
\[
\left\langle \tilde{g}_i(\theta_i^{r+1}) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle
= \left\langle \tilde{g}_i(\theta_i^{r+1}) - g_i(\theta_i^{r+1}) + g_i(\theta_i^{r+1}) - g_i(\theta_i^r) + g_i(\theta_i^r) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle.
\]
\[
\leq \frac{\gamma}{2} ||\lambda_i^{r+1} - \lambda_i^r||^2 + \left\langle \tilde{g}_i(\theta_i^{r+1}) - g_i(\theta_i^{r+1}), \lambda_i^{r+1} - \lambda_i^r \right\rangle + \left\langle \tilde{g}_i(\theta_i^r) - g_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \right\rangle + \frac{L^2}{2\gamma^r} ||\theta_i^{r+1} - \theta_i^r||^2. \tag{89}
\]
Third, taking expectation on both sides over (88) and summing over \( i \), we have
\[
\frac{1}{2\rho} \mathbb{E} ||\lambda^{r+1} - \lambda^r||^2 - \frac{\gamma^r - \gamma^{-1}}{2} \mathbb{E} ||\lambda^{r+1}||^2
\leq (a) \frac{1}{2\rho} \mathbb{E} ||\lambda^r - \lambda^{r-1}||^2 - \frac{\gamma^r - \gamma^{-1}}{2} \mathbb{E} ||\lambda^r||^2 - \gamma^r \mathbb{E} ||\lambda^{r+1} - \lambda^r||^2
\]
\[
+ \frac{L^2}{2\gamma^r} \mathbb{E} ||\theta^{r+1} - \theta^r||^2 + \rho \sigma_g^2(T, K) + 4n \epsilon_g(T) \sigma_\lambda, \tag{90}
\]
where (a) uses the same argument as in (81) to quantify \( \mathbb{E} \langle g_i(\theta_i^r) - \tilde{g}_i(\theta_i^r), \lambda_i^{r+1} - \lambda_i^r \rangle \) and Lemma 6.
Finally, multiplying by $4$ and dividing by $\rho \gamma^r$ on the both sides of the above equation, we arrive at

\[
\frac{2}{\rho \gamma^r} \mathbb{E}\|\lambda^{r+1} - \lambda^r\|^2 - \frac{2}{\rho} \left( \frac{\gamma^{r-1}}{\gamma^r} - 1 \right) \mathbb{E}\|\lambda^{r+1}\|^2 \\
\leq \frac{2}{\rho^2 \gamma^r} \mathbb{E}\|\lambda^r - \lambda^{r-1}\|^2 - \frac{2}{\rho} \left( \frac{\gamma^{r-2}}{\gamma^{r-1}} - \frac{\gamma^{r-1}}{\gamma^r} - 1 \right) \mathbb{E}\|\lambda^r\|^2 \\
+ \frac{2}{\rho} \left( \frac{1}{\gamma^r} - \frac{1}{\gamma^{r-1}} \right) \mathbb{E}\|\lambda^r - \lambda^{r-1}\|^2 + \frac{2}{\rho} \left( \frac{\gamma^{r-2}}{\gamma^{r-1}} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E}\|\lambda^r\|^2 \\
- \frac{2}{\rho} \mathbb{E}\|\lambda^{r+1} - \lambda^r\|^2 + \frac{2L^2}{\rho^2 \gamma^r} \mathbb{E}\theta^{r+1} + \mathbb{E}\theta^r \mathbb{E}\|\theta^{r+1} - \theta^r\|^2 + \frac{4}{\rho \gamma^r} \left( \rho \sigma^2_g(T, K) + 4n\epsilon_g(T)\sigma_L \right). 
\] (91)

\[
\frac{1}{\gamma^{r+1}} - \frac{1}{\gamma^r} \leq \frac{1}{5}, 
\] (93)

**Potential Function and Convergence Rate**

From Lemma 4, it can be seen that the descent lemma is built upon the function value evaluated at the consensus space, i.e., $\tilde{\theta}^r$, while the ascent lemma is based on the function value evaluated at individual variables at each node, i.e., $\{\theta_i^r, \lambda_i^r\}$. To show the convergence of the iterates, we need some function to link the descent provided by the primal variable update and the ascent obtained by the dual update and the contraction achieved by the PG tracking update. In other words, the step sizes involved in (10) and (13) are required to be controlled properly so that ascent of the (potential) function value is dominated by the descent and contraction.

Combining the descent lemma (i.e., Lemma 4), contraction lemma (i.e., Lemma 5), and ascent lemma (i.e., Lemma 7) leads to the following lemma.

**Potential function**

**Lemma 9.** (Potential/Lyapunov-like function) Under Assumption 1 to Assumption 4, suppose that the decreasing sequence $\gamma^r$ satisfies

\[
0 < \varphi < 1, \nu \leq \left( \frac{1}{2\varphi} - 1 \right) / 2, \text{and } \beta^r \leq \min\{\beta_1, \beta_2, \beta_3\}, \text{where } \beta_1, \beta_2, \beta_3 \text{ are defined in (118) – (120). Then, there exist constants } a_1, a_2, a_3 > 0 \text{ such that}
\]

\[
P^{r+1} \leq P^r - a_1 \beta^r \mathbb{E}\|\tilde{\theta}^r\|^2 - \frac{a_2}{n} \mathbb{E}\|\theta^r - 1\theta^r\|^2 - \frac{a_3}{n} \mathbb{E}\|\tilde{\theta}^r\|^2 - \frac{\mathcal{U}^r}{10\rho n} \mathbb{E}\|\lambda^{r+1} - \lambda^r\|^2 \\
+ 2\mathcal{U}^r \left( \frac{\gamma^{r-2}}{\gamma^{r-1}} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E}\|\lambda^r\|^2 + \mathcal{U}^r \frac{\gamma^{r-1} - \gamma^r}{2n} \mathbb{E}\|\lambda^{r+1}\|^2 \\
+ (\mathcal{U}^r - \mathcal{U}^{r+1}) \frac{\gamma^r}{2n} \mathbb{E}\|\lambda^{r+1}\|^2 + (\mathcal{U}^{r+1} - \mathcal{U}^r) \frac{1}{n} \sum_{i=1}^n \mathbb{E}l_i(\tilde{\theta}^{r+1}, \lambda_i^{r+1}) + \mathcal{U}^r \frac{\sigma^2_g}{n} \\
+ \mathcal{U}^r \left( \frac{\rho \sigma^2_g(T, K)}{n} + 4\epsilon_g(T)\sigma_L \right) \left( 1 + \frac{4}{\rho} \right) f(\tilde{\theta}^r, \lambda^r, \mathcal{U}^r) + \epsilon_f(T) + \sigma^\prime \mathcal{U}^r(T, K) 
\] (94)

where the potential function $P^r$ is defined as below

\[
P^r \triangleq \mathcal{U}^r \mathcal{W}^r + \mathbb{E}[f(\tilde{\theta}^r, \lambda^r)] + \frac{1}{n} \mathbb{E}\|\theta^r - 1\theta^r\|^2 + \frac{\beta^r}{n} \mathbb{E}\|\theta^r - 1\theta^r\|^2, 
\]
and

\[
\mathcal{R}^r \triangleq Q^r - \frac{\gamma^r}{2n} \mathbb{E}[\|\mathbf{x}^r\|^2] + \frac{1}{2\rho} \mathbb{E}[\|\mathbf{x}^r - \mathbf{x}^{r-1}\|^2],
\]

(95a)

\[
\mathcal{W}^r \triangleq \mathcal{R}^r + \frac{1}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma^r)^2} \right) \mathbb{E}[\|\mathbf{\theta}^r - \mathbf{\bar{\theta}}\|^2],
\]

(95b)

\[
\mathcal{U}^r \triangleq \frac{\rho(\gamma^r+1)^2}{\rho(\gamma^0)^2(3\rho L^2 + L^2) + 12L^2 + 1n \nu^2},
\]

(95c)

\[
\mathcal{V}^r(T, K) \triangleq 3 \left( 2k + \frac{1}{n} \left( \frac{\beta^r}{\gamma^r+1} \right) \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] + \frac{4L^2(\beta^r)^3}{\nu} \left( 1 + \frac{1}{\nu} \right)^2 \kappa \sigma^2(T, K) \right) + \frac{\beta^r}{\gamma^r+1} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2],
\]

(95d)

From Lemma 9, it is clear that the size of PG, i.e., \(\|\mathbf{\theta}^r\|\), consensus violation, i.e., \(\|\mathbf{\theta}^r - \mathbf{\bar{\theta}}\|\), tracking accuracy, i.e., \(\|\mathbf{x}^r - \mathbf{x}\|\), and difference of the dual variable at two successive iterates, i.e., \(\|\mathbf{x}^{r+1} - \mathbf{x}^r\|\) will jointly determine the progress of Safe Dec-PG. Note that the all the constants in front of these terms are negative. Therefore, potential function \(P^r\) is decreasing up to some error terms that can be bounded by shrinking the stepsize after applying the telescoping sum.

**Proof. First step:** Constructing the potential function for the maximization step.

Combining Lemma 7 and Lemma 8, we can have

\[
\begin{align*}
\mathcal{R}^{r+1} + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_i(\mathbf{\theta}_i^{r+1}, \mathbf{x}_i^{r+1}) \\
\leq \mathcal{R}^r + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_i(\mathbf{\theta}_i^{r+1}, \mathbf{x}_i^r) - \frac{1}{2\rho} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] + \frac{1}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma^r)^2} \right) \mathbb{E}[\|\mathbf{\theta}^{r+1} - \mathbf{\theta}^r\|^2] \\
+ \frac{\gamma^r - \gamma^r}{2n} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] + \frac{2}{\rho} \left( \frac{1}{\gamma^r+1} - \frac{1}{\gamma^r} \right) \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] + \frac{2}{\rho} \left( \frac{\gamma^r-2}{\gamma^r-1} - \frac{\gamma^r-1}{\gamma^r} \right) \mathbb{E}[\|\mathbf{x}^r\|^2] \\
+ \left( \frac{\rho}{n} \sigma^2(T, K) + 4\epsilon_\beta(T)\sigma_\lambda \right) \left( 1 + \frac{4}{\gamma^r} \right). \tag{96}
\end{align*}
\]

where

\[
\mathcal{R}^{r+1} = Q^{r+1} - \frac{\gamma^r}{2n} \mathbb{E}[\|\mathbf{x}^{r+1}\|^2] + \frac{1}{2\rho} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2].
\]

(97)

When \(1/\gamma^{r+1} - 1/\gamma^r \leq 1/5\), we have \(-1/2\rho + \frac{2}{\rho}(1/\gamma^{r+1} - 1/\gamma^r) < 0\).

Thus, we can get

\[
\begin{align*}
\mathcal{R}^{r+1} + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_i(\mathbf{\theta}_i^{r+1}, \mathbf{x}_i^{r+1}) \\
\leq \mathcal{R}^r + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_i(\mathbf{\theta}_i^{r+1}, \mathbf{x}_i^r) - \frac{1}{2\rho} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] - \frac{1}{10\rho} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] \\
+ \frac{\gamma^r - \gamma^r}{2n} \mathbb{E}[\|\mathbf{x}^{r+1} - \mathbf{x}^r\|^2] + \frac{2}{\rho} \left( \frac{\gamma^r-2}{\gamma^r-1} - \frac{\gamma^r-1}{\gamma^r} \right) \mathbb{E}[\|\mathbf{x}^r\|^2] \\
+ \frac{1}{n} \left( \rho \sigma^2(T, K) + 4n\epsilon_\beta(T)\sigma_\lambda \right) \left( 1 + \frac{4}{\gamma^r} \right). \tag{98}
\end{align*}
\]

**Second step:** get the upper bound of \(\|\mathbf{\theta}^{r+1} - \mathbf{\theta}^r\|^2\) in terms of the disagreement between \(\mathbf{\theta}^r\) and \(\mathbf{\bar{\theta}}^r\).

Note that

\[
\|\mathbf{\theta}^{r+1} - \mathbf{\theta}^r\|^2 \leq 3\|\mathbf{\theta}^{r+1} - \mathbf{\bar{\theta}}^{r+1}\|^2 + 3n\|\mathbf{\theta}^{r+1} - \mathbf{\theta}^r\|^2 + 3\|\mathbf{\theta}^r - \mathbf{\bar{\theta}}^r\|^2, \tag{99}
\]

and

\[
\|\mathbf{\theta}^{r+1} - \mathbf{\theta}^r\|^2 = (\beta^r)^2\|\mathbf{\theta}^r\|^2, \quad \mathbb{E}[\|\mathbf{\theta}^r - \mathbf{\bar{\theta}}^r\|^2] \leq \frac{\sigma^2(T, K)}{n}. \tag{100}
\]
Combining (99) and (100), we can have

\[
\frac{1}{n} \mathbb{E}[\theta^{r+1} - \theta^r]^2 \leq \frac{3}{n} \mathbb{E}[\theta^{r+1} - \mathbf{1}\theta^{r+1}]^2 + \frac{3}{n} \mathbb{E}[\theta^r - \mathbf{1}\theta^r]^2 + 3(\beta^r)^2 \mathbb{E}[\theta^r]^2 + \frac{3}{n} (\beta^r)^2 \sigma_f^2(T, K). \tag{101}
\]

**Third step:** replace \( \mathbb{E}[\theta^{r+1} - \theta^r]^2 \) in (98) by a recursive formula in terms of \( \mathbb{E}[\theta^{r+1} - \mathbf{1}\theta^{r+1}]^2 \) and \( \mathbb{E}[\theta^r - \mathbf{1}\theta^r]^2 \).

Adding

\[
\frac{3}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho (\gamma^r+1)^2} \right) \mathbb{E}[\theta^{r+1} - \mathbf{1}\theta^{r+1}]^2
\]

\( \triangleq \mathcal{R}^{r+1} \)
on the both sides of (98) and applying (101), we arrive at

\[
\mathcal{R}^{r+1} + \frac{1}{n} \sum_{i=1}^n \mathbb{E}[l_i(\theta_i^{r+1}, \lambda_i^{r+1})] + \mathcal{R}^{r+1} \mathbb{E}[\theta^{r+1} - \mathbf{1}\theta^{r+1}]^2
\]

\[
\leq \mathcal{R}^r + \frac{1}{n} \sum_{i=1}^n \mathbb{E}[l_i(\theta_i^{r+1}, \lambda_i^r)] + \mathcal{R}^r \mathbb{E}[\theta^r - \mathbf{1}\theta^r]^2
\]

\[
+ \frac{3}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho (\gamma^r)^2} \right) \mathbb{E}[\theta^r]^2 - \frac{1}{10\rho n} \mathbb{E}[\lambda^{r+1} - \lambda^r]^2
\]

\[
+ \frac{\gamma^r - \gamma^r}{2n} \mathbb{E}[\lambda^{r+1}]^2 + \frac{1}{\rho n} \left( \gamma^r - 1 \right) \mathbb{E}[\lambda^r]^2 + \frac{3(\beta^r)^2}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho (\gamma^r)^2} \right) \sigma_f^2(T, K)
\]

\[
+ \left( \frac{\rho}{\rho n} \sigma_f^2(T, K) + 4\epsilon_g(T)\sigma_\lambda \right) \left( 1 + \frac{4}{\gamma^r} \right).
\tag{103}
\]

**Fourth step:** make a connection between the changes of the loss functions evaluated at the individual node, i.e.,

\( l_i(\theta_i^{r+1}, \lambda_i^{r+1}) - l_i(\theta_i^r, \lambda_i^r), \forall i \), and the changes of the loss function evaluated at the consensus space, i.e.,

\( l_i(\theta_i^{r+1}, \lambda_i^{r+1}) - l_i(\theta_i^{r+1}, \lambda_i^r), \forall i \).

According to the Lipschitz continuity of \( g_i(\cdot), \forall i \) and Young’s inequality, we have

\[
\langle \lambda_i^{r+1}, g_i(\theta_i^{r+1}) \rangle - \langle \lambda_i^r, g_i(\theta_i^r) \rangle \leq \frac{||\lambda_i^{r+1}||^2}{2} + \frac{L^2||\theta_i^{r+1} - \theta_i^r||^2}{2},
\tag{104}
\]

which implies

\[
\sum_{i=1}^n l_i(\theta_i^{r+1}, \lambda_i^{r+1}) - \sum_{i=1}^n l_i(\theta_i^{r+1}, \lambda_i^r)
\]

\[
\leq \sum_{i=1}^n l_i(\theta_i^{r+1}, \lambda_i^{r+1}) - \sum_{i=1}^n l_i(\theta_i^{r+1}, \lambda_i^r) + \frac{||\lambda_i^{r+1}||^2 + ||\lambda_i^r||^2}{2} + L^2||\theta_i^{r+1} - \theta_i^r||^2
\]

\[
\leq \sum_{i=1}^n l_i(\theta_i^{r+1}, \lambda_i^{r+1}) - \sum_{i=1}^n l_i(\theta_i^{r+1}, \lambda_i^r) + \sigma_\lambda^2 + L^2||\theta_i^{r+1} - \theta_i^r||^2
\tag{105}
\]

where in (a) we apply Assumption 4.

**Fifth step:** merge step 3 and step 4 to construct a potential function.

Let

\[
\mathcal{W}^{r+1} \triangleq \mathcal{R}^{r+1} + \mathcal{R}^{r+1} \mathbb{E}[\theta^{r+1} - \mathbf{1}\theta^{r+1}]^2 = \mathcal{R}^r + \frac{3}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho (\gamma^r+1)^2} \right) \mathbb{E}[\theta^r - \mathbf{1}\theta^r]^2
\]

\( \tag{106} \)

and

\[
S^r = 3 \left( \rho L^2 + \frac{2L^2}{\rho} \left( \frac{1}{(\gamma^r)^2} + \frac{1}{(\gamma^r+1)^2} \right) \right).
\tag{107} \]
Sixth step: scale the current potential function by $U$

Applying (108), we have

\[\mathcal{W}^{r+1} + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E} l_i(\theta^{r+1}, \lambda_i^{r+1}) \]

\[\leq \mathcal{W}^{r} + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E} l_i(\theta^{r+1}, \lambda_i^{r}) + \frac{1}{n}(S^r + L^2)\mathbb{E}\|\theta^{r+1} - 1\theta^r\|^2 \]

\[+ 3(\beta^r)^2 \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma^r)^2} \right) \mathbb{E}||\theta^r||^2 - \frac{1}{10\rho n} \mathbb{E}||\lambda^{r+1} - \lambda^{r}||^2 + \frac{\gamma^{r-1} - \gamma^r}{2n} \mathbb{E}||\lambda^{r+1}||^2 \]

\[+ \frac{2}{\rho n} \left( \frac{\gamma^r - 1}{\gamma^r - 1} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E}||\lambda^{r}||^2 + \frac{3(\beta^r)^2}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma^r)^2} \right) \sigma^2(T, K) \]

\[+ \left( \frac{\rho}{n} \sigma^2_g(T, K) + 4\epsilon_g(T)\sigma_\lambda \right) \left( 1 + \frac{4}{\gamma^r \rho} \right) . \]  

(108)

Applying (58), we have

\[\mathcal{W}^{r+1} + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E} l_i(\theta^{r+1}, \lambda_i^{r+1}) \]

\[\leq \mathcal{W}^{r} + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E} l_i(\theta^{r+1}, \lambda_i^{r}) + \frac{1}{n}(S^r + L^2)(1 + \nu)\mathbb{E}\|\theta^r - 1\theta^r\|^2 \]

\[+ \frac{3}{n} \left( S^r + L^2 \right) \left( 1 + \frac{1}{\nu} \right) (\beta^r)^2 \mathbb{E}||\theta^r - 1\theta^r||^2 + 3(\beta^r)^2 \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma^r)^2} \right) \mathbb{E}||\theta^r||^2 \]

\[- \frac{1}{10\rho n} \mathbb{E}||\lambda^{r+1} - \lambda^{r}||^2 + \frac{\gamma^{r-1} - \gamma^r}{2n} \mathbb{E}||\lambda^{r+1}||^2 + \frac{2}{\rho n} \left( \frac{\gamma^r - 1}{\gamma^r - 1} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E}||\lambda^{r}||^2 \]

\[+ \left( 2(S^r + L^2) \left( 1 + \frac{1}{\nu} \right) \kappa + \frac{1}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma^r)^2} \right) \right) 3(\beta^r)^2 \sigma^2_g(T, K) \]

\[+ \sigma^2 + \left( \frac{\rho}{n} \sigma^2_g(T, K) + 4\epsilon_g(T)\sigma_\lambda \right) \left( 1 + \frac{4}{\gamma^r \rho} \right) . \]  

(109)

Sixth step: scale the current potential function by $U^r$ such that it will have some contraction property in (117).

Note that

\[\frac{\nu}{1 + \nu} \frac{1}{S^r + L^2} \geq \frac{\nu}{1 + \nu} \frac{1}{3\rho L^2 + L^2 + 6L^2/\rho(r^{r+1})^2}. \]  

(110)

\[\geq \frac{\nu}{1 + \nu} \frac{1}{\rho(r^{r+1})^2} \]

(111)

\[\geq \frac{\nu}{1 + \nu} \frac{1}{\rho(r^{r+1})^2} (3\rho L^2 + L^2) + 12L^2 \]

(112)

Thus, it is straightforward that

\[U^r(S^r + L^2)(1 + \nu) \leq \nu. \]  

(113)

Then, multiplying by $U^r$ both sides of (109), we can easily obtain

\[U^r \mathcal{W}^{r+1} + \frac{1}{n} \sum_{i=1}^{n} U^r \mathbb{E} l_i(\theta^{r+1}, \lambda_i^{r+1}) \]

\[\leq (a) U^r \mathcal{W}^{r} + \frac{1}{n} \sum_{i=1}^{n} U^r \mathbb{E} l_i(\theta^{r+1}, \lambda_i^{r}) + \frac{\nu}{n} \mathbb{E}||\theta^r - 1\theta^r||^2 + \frac{3(\beta^r)^2}{n} \mathbb{E}||\theta^r - 1\theta^r||^2 \]

\[+ (\beta^r)^2 \frac{\nu}{1 + \nu} \mathbb{E}||\theta^r||^2 - \frac{U^r}{10\rho n} \mathbb{E}||\lambda^{r+1} - \lambda^{r}||^2 + U^r \frac{\gamma^{r-1} - \gamma^r}{2n} \mathbb{E}||\lambda^{r+1}||^2 \]

\[+ \frac{2U^r}{\rho n} \left( \frac{\gamma^r - 1}{\gamma^r - 1} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E}||\lambda^{r}||^2 \]

\[+ 3 \left( 2\kappa + \frac{1}{n} \right) (\beta^r)^2 \sigma^2_g(T, K) + U^r \sigma^2 + U^r \left( \frac{\rho}{n} \sigma^2_g(T, K) + 4\epsilon_g(T)\sigma_\lambda \right) \left( 1 + \frac{4}{\gamma^r \rho} \right) , \]  

(114)
where (a) uses the fact that \(3(\rho L^2/2 + \frac{2L^2}{\rho(\gamma r)^2}) < S\) and \(\nu < 1\).

From (83), (97), and (106), we know

\[
W^{r+1} = \frac{1}{n} \left( \frac{2}{\rho r} + \frac{1}{2\rho} \right) ||\lambda^{r+1} - \lambda^r||^2 + \frac{3}{n} \left( \frac{\rho L^2}{2} + \frac{2L^2}{\rho(\gamma r+1)^2} \right) ||\theta^{r+1} - 1\theta^{r+1}||^2 \\
- \frac{2}{\rho n} \left( \frac{\gamma^{r-1}}{\gamma r} - 1 \right) ||\lambda^{r+1}||^2 - \frac{\gamma r}{2n} ||\lambda^{r+1}||^2. 
\]  

(115)

Since \(\gamma^r\) is diminishing, \(U^r\) is also decreasing. Then, by adding \(\frac{1}{n} \sum_{i=1}^n U^{r+1}E_i(\bar{\theta}^{r+1}, \lambda^{r+1})\) and \(U^{r+1}W^{r+1}\) both sides of (114), we have

\[
U^{r+1}W^{r+1} + \frac{1}{n} \sum_{i=1}^n U^{r+1}E_i(\bar{\theta}^{r+1}, \lambda^{r+1}) \\
\leq U^rW^r + \frac{1}{n} \sum_{i=1}^n U^rE_i(\bar{\theta}^{r+1}, \lambda^r) + \frac{\nu n^2}{n} ||\theta^r - 1\theta^r||^2 + \frac{3(\beta^r)^2}{n} ||\theta^r - 1\theta^r||^2 \\
+ (\beta^r)^2 \frac{\nu}{1 + \nu} E||\bar{\theta}^r||^2 - \frac{U^r}{10\rho n} E||\lambda^{r+1} - \lambda^r||^2 + U^r \frac{\gamma^{r-1} - \gamma^r}{2n} E||\lambda^{r+1}||^2 \\
+ 2U^r \left( \frac{\gamma^{r-1} - \gamma^r}{\gamma r-1} \right) E||\lambda^r||^2 + 3 \left( 2\kappa + \frac{1}{n} \right) (\beta^r)^2 \sigma^2(T, K) + U^r \sigma^2_{\lambda} \\
+ U^r \left( \frac{\rho}{n} \sigma^2_g(T, K) + 4\epsilon_g(T)\sigma_{\lambda} \right) \left( 1 + \frac{4}{\gamma^r r} \right) + (U^r - U^{r+1}) \frac{\gamma^r}{2n} ||\lambda^{r+1}||^2 \\
+ (U^{r+1} - U^r) \frac{1}{n} \sum_{i=1}^n E_i(\bar{\theta}^{r+1}, \lambda^{r+1})  
\]  

(116)

where (a) uses the fact that \(U^{r+1}W^{r+1} - U^rW^r \leq (U^r - U^{r+1}) \gamma^r ||\lambda^{r+1}||^2/(2n)\).

**Seventh step:** merge descent (Lemma 4) and contraction (Lemma 5) into the potential function.
Combining (54), (58), and (59), gives rise to

\[
\mathcal{U}^{r+1} \mathcal{W}^{r+1} + \mathbb{E} \left[ f(\theta^{r+1}, \mathcal{U}^{r+1} \chi^{r+1}) \right] + \frac{1}{n} \mathbb{E} \left\| \theta^{r+1} - 1 \theta^{r+1} \right\|^2 + \frac{\beta^{r+1}}{n} \mathbb{E} \left\| \theta^{r+1} - 1 \theta^{r+1} \right\|^2 \\
\leq \mathcal{U}^{r} \mathcal{W}^{r} + \mathbb{E} \left[ f(\theta^{r}, \mathcal{U}^{r} \chi^{r}) \right] + \frac{1}{n} \mathbb{E} \left\| \theta^{r} - 1 \theta^{r} \right\|^2 + \frac{\beta^{r}}{n} \mathbb{E} \left\| \theta^{r} - 1 \theta^{r} \right\|^2 \\
- \beta^{r} \left( 1 - \left( \frac{\varphi}{2} + \beta^{r} L + 4L^2 \beta^{r} \left( 1 + \frac{1}{\nu} \right)^2 + \beta^{r} \rho \frac{1}{1+\nu} \right) \right) \mathbb{E} \left\| \theta^{r} \right\|^2 \\
\leq \frac{1}{n} \left( 1 - \left( (1+\nu) \eta^2 + \nu \eta^2 + \frac{\beta^{r} L^2}{2 \varphi} \rho + \beta^{r} \left( L^2 \eta^2 (1+\nu) \left( 1 + \frac{1}{\nu} \right) + 4L^2 \left( 1 + \frac{1}{\nu} \right)^2 \right) \right) \right) \mathbb{E} \left\| \theta^{r} - 1 \theta^{r} \right\|^2 \\
- \frac{\beta^{r}}{n} \left( 1 - \left( (1+\nu) \eta^2 + 4L^2 (\beta^{r})^2 \left( 1 + \frac{1}{\nu} \right)^2 + 3 \left( 1 + \frac{1}{\nu} \right) \beta^{r} + 3 \beta^{r} \right) \right) \mathbb{E} \left\| \theta^{r} - 1 \theta^{r} \right\|^2 \\
- \frac{\mathcal{U}^{r}}{10 \rho n} \mathbb{E} \left\| \lambda^{r+1} - \chi^{r+1} \right\|^2 + \mathcal{U}^{r} \gamma^{r-1} - \gamma^r \mathbb{E} \left\| \lambda^{r+1} \right\|^2 \\
+ \frac{2 \mathcal{U}^{r}}{\rho n} \left( \frac{\gamma^{r-2}}{\gamma^{r-1}} - \frac{\gamma^{r-1}}{\gamma^r} \right) \mathbb{E} \left\| \lambda^{r+1} \right\|^2 + 3 \left( 2 \kappa + \frac{1}{n} \right) (\beta^{r})^2 \sigma_f^2 (T, K) + \mathcal{U}^{r} \sigma_{\chi}^2 \\
+ \mathcal{U}^{r} \left( \frac{\beta^{r}}{n} \sigma_f^2 (T, K) + 4 \epsilon_f (T) \sigma_{\chi} \right) \left( 1 + \frac{4}{\gamma^r \rho} \right) + 4L^2 (\beta^{r})^3 \left( 1 + \frac{1}{\nu} \right)^2 \kappa \sigma_f^2 (T, K) \\
+ \frac{(\beta^{r})^2 \lambda \sigma_f^2 (T, K)}{n} + \| \nabla f(\theta^{r}, \mathcal{U}^{r} \chi^{r}) \| \epsilon_f (T) + 6 \left( 1 + \frac{1}{\nu} \right) (\beta^{r})^2 \kappa \sigma_f^2 (T, K) \\
+ (\mathcal{U}^{r} - \mathcal{U}^{r+1}) \gamma^{r} \mathbb{E} \left\| \lambda^{r+1} \right\|^2 + \left( \mathcal{U}^{r+1} - \mathcal{U}^{r} \right) \frac{1}{n} \sum_{i=1}^{n} \mathcal{E}_{i} \left( \theta^{r+1} - 1 \theta^{r+1} \right),
\] (117)

where we have also used the fact that $\beta^r$ is decreasing, i.e., $(\beta^{r+1} - \beta^{r}) \| \theta^{r+1} - 1 \theta^{r+1} \|^2 < 0$.

To get the descent of the potential function, we require that $a_1, a_2, a_3$ all be positive.

First, if

$$\varphi < 1, \quad \beta^{r} \leq \frac{1}{2(L + 4L^2(1 + \nu)^2 + \nu/(1 + \nu))} \triangleq \beta_1,$$ (118)

then, we have $a_1 > 0$.

Second, let $\nu_1 \triangleq \frac{1}{2} \left( \frac{1}{2\nu^2} - 1 \right)$. Obviously, when $\nu < \nu_1$, we have $(1 + 2\nu) \eta^2 < 1/2$. In this case, if

$$\beta^{r} \leq \frac{1}{2} \left( \frac{1}{2\nu^2} + L^2 \eta^2 (1 + \nu)(1 + \nu^{-1}) + 4L^2 (1 + \nu^{-1})^2 \right) \triangleq \beta_2,$$ (119)

then, we have $a_2 > 0$.

Third, let $\nu_2 \triangleq 1/(2\eta^2) - 1$. If $\nu < \nu_2$, we have $(1 + \nu) \eta^2 < 1/2$. In this case, if

$$\beta^{r} < \frac{-3(2 + 1/\nu) + \sqrt{3(2 + 1/\nu)^2 + 8L^2(1 + 1/\nu)^2}}{8L^2(1 + 1/\nu)^2} \triangleq \beta_3,$$ (120)

then, we have $a_3 > 0$.

We take $\varphi < 1, \nu \leq \min\{\nu_1, \nu_2\} = \frac{1}{2} \left( \frac{1}{2\nu^2} - 1 \right)$ and $\beta^{r} \leq \min\{\beta_1, \beta_2, \beta_3\}$. 

\[\square\]
Remark 6. Lemma 9 indicates that there is an upper bound of $\beta^r$ (which is independent on $n$). Later, we will see that $\beta^r$ should also be a decreasing sequence. For simplicity, we take the decreasing sequence $\{\beta^r, \forall r\}$ (the following choice can guarantee the convergence of the algorithm) as

$$\beta^r \triangleq \frac{\beta^0}{\sqrt{n}},$$  \hspace{1cm} (121)

where $\beta^0 \triangleq \min\{\beta_1, \beta_2, \beta_3\}$.

**Proof of Theorem 1**

The constructed potential function measures the progress of the algorithm. From Lemma 9, it is clear that $P^r$ would be decreasing if the size of the positive error terms could be dominated by the size of the negative terms. Next, we provide the detailed technical proof of the convergence rate of Safe Dec-PG as the following.

**Proof. First step:** get an upper bound of the optimality gap:

$$G_i(\{\theta^r_i, \lambda^r_i, \forall i\}) = \left[ \frac{1}{n} \sum_{i=1}^{n} \nabla f_i(\theta^r_i, \lambda^r_i) \right]_{\text{minimization error}} + \left[ \frac{1}{n} \sum_{i=1}^{n} \|\lambda^r_i - \lambda^r + \rho_i(\lambda^r_i + g_i(\theta^r_i))\| \right]_{\text{maximization error}} + \left[ \frac{1}{n} \sum_{i=1}^{n} \|\theta^r_i - \bar{\theta}^r\| \right]_{\text{consensus violation error}}$$

\[= \|\bar{\theta}^r\| + \frac{1}{n} \sum_{i=1}^{n} \|\lambda^r_i - \lambda^r\| + \|\lambda^r_i - \lambda^r + \rho_i(\lambda^r_i + g_i(\theta^r_i))\| + \|\theta^r_i - \bar{\theta}^r\| \leq \|\bar{\theta}^r\| + \frac{1}{n} \sum_{i=1}^{n} \|\lambda^r_i - \lambda^r\| + \|\lambda^r_i + g_i(\theta^r_i)\| + \|\theta^r_i - \bar{\theta}^r\| \]

Then, we have

$$E[G_i^2(\{\theta^r_i, \lambda^r_i, \forall i\})] \leq \left(\frac{4n + 2}{n^2}\right) \left( E[\|\bar{\theta}^r\|^2] + (\gamma)^2 E[\lambda^r_i + g_i(\theta^r_i)]^2 + E[\theta^r - \bar{\theta}^r]^2 \right)$$

\[+ \left(1 + \frac{1}{\rho}\right)^2 E[\lambda^r_i - \lambda^r]^2 + L^2 E[\theta^r_i - \bar{\theta}^r]^2 + n\sigma^2(T, K) \]n \leq \left(\frac{4n + 2}{n^2}\right) \left(1 + 3nL^2(\beta^r)^2\right) E[\|\bar{\theta}^r\|^2] + \left(1 + \frac{1}{\rho}\right)^2 E[\lambda^r_i - \lambda^r]^2 + n\sigma^2(T, K) \]

$$+ (\gamma)^2 E[\lambda^r_i + g_i(\theta^r_i)]^2 + 3L^2 E[\theta^r_i - \bar{\theta}^r]^2 + E[\theta^r - \bar{\theta}^r]^2 + 3(\beta^r)^2 L^2 \sigma_j^2(T, K) \] \hspace{1cm} (124)$$

where (a) applies Young’s inequality, Lipschitz continuity and Lemma 2.
Due to the fact that $\|\lambda^r\|^2$ is upper bounded by $n\sigma_\lambda^2$, by applying (58), we have

$$
\mathbb{E}[G^2(\theta^r, \lambda^r)] \\
\leq \frac{4n + 2}{n^2} \left(1 + 3nL^2(\beta^r)^2\mathbb{E}\|\tilde{\theta}^r\|^2 + \left(1 + \frac{1}{\nu}\right)^2 \mathbb{E}||\lambda^{r+1} - \lambda^r||^2 \right. \\
+ 3L^2 \left((1 + \nu)\eta^2 + 1\right) \mathbb{E}||\theta^r - 1\tilde{\theta}^r||^2 \\
+ 9L^2 \left(1 + \frac{1}{\nu}\right)(\beta^r)^2 \mathbb{E}||\theta^r - 1\tilde{\theta}^r||^2 + 18L^2 \left(1 + \frac{1}{\nu}\right)(\beta^r)^2 \kappa \sigma_f(T, K) \\
+ n\sigma_\lambda^2(T, K) + (\gamma^r)^2 n\sigma_\lambda^2 + 3(\beta^r)^2 L^2 \sigma_f^2(T, K). 
$$

(125)

Note that $\beta^r$ is decreasing, we only need to take

$$
\Theta \triangleq \left(4 + \frac{2}{n}\right) \max\left\{\frac{1}{n} + 3L^2(\beta^0)^2, \left(1 + \frac{1}{\nu}\right)^2, 3L^2(1 + (1 + \nu)\eta^2), 9L^2 \left(1 + \frac{1}{\nu}\right)(\beta^0)^2\right\} 
$$

so that

$$
\mathbb{E}[G^2(\theta^r, \lambda^r)] \\
\leq \Theta \left(\mathbb{E}\|\tilde{\theta}^r\|^2 + \frac{1}{n} \mathbb{E}\|\lambda^{r+1} - \lambda^r\|^2 + \frac{1}{n} \mathbb{E}||\theta^r - 1\tilde{\theta}^r||^2 + \frac{1}{n} \mathbb{E}||\theta^r - 1\tilde{\theta}^r||^2\right) \\
\leq \Theta \left(18 \left(1 + \frac{1}{\nu}\right) \kappa + 3\right) L^2(\beta^r)^2 \sigma_f^2(T, K) + n\sigma_\lambda^2(T, K) + (\gamma^r)^2 n\sigma_\lambda^2. 
$$

(126)

**Second step:** get an upper bound of $\mathcal{H}^r$

From (117), we have

$$
\beta^r a_1 \mathbb{E}\|\tilde{\theta}^r\|^2 + a_2 \frac{1}{n} \mathbb{E}||\theta^r - 1\tilde{\theta}^r||^2 + a_3 \frac{\beta^r}{n} \mathbb{E}||\theta^r - 1\tilde{\theta}^r||^2 + \frac{\mathcal{U}^r}{10\rho n} \mathbb{E}||\lambda^{r+1} - \lambda^r||^2 \\
\leq (\mathcal{P}^r - \mathcal{P}^{r+1}) + \mathcal{U}^r \gamma^{r-1} - \gamma^r \mathbb{E}||\lambda^{r+1}||^2 + \frac{2\mathcal{U}^r}{\rho n} \left(\frac{\gamma^{r-2} - \gamma^{r-1}}{\gamma^r}\right) \mathbb{E}||\lambda^r||^2 \\
+ (\mathcal{U}^r - \mathcal{U}^{r+1}) \frac{\gamma^r}{2n} \mathbb{E}||\lambda^{r+1}||^2 + \mathcal{U}^r \left(\frac{\beta^r}{n} \sigma_f^2(T, K) + 4\epsilon_g(T)\sigma_\lambda\right) \left(1 + \frac{4}{\gamma^r \rho}\right) \\
+ \mathcal{U}^r \sigma_\lambda^2 + \epsilon_f(T)\mathbb{E}||\nabla f(\bar{\theta}^r, \mathcal{U}^r \lambda^r)|| + (\mathcal{U}^{r+1} - \mathcal{U}^r) \frac{1}{n} \sum_{i=1}^n \mathbb{E}\langle g_i(\theta^{r+1}), \lambda_i^{r+1}\rangle \\
+ \left(3 \left(2\kappa + \frac{1}{n}\right) + \frac{L}{n} + 6 \left(1 + \frac{1}{\nu}\right) \kappa + 4L^2 \beta^r \left(1 + \frac{1}{\nu}\right)^2 \kappa\right) (\beta^r)^2 \sigma_f^2(T, K). 
$$

(128)

Here, we require that the shrinking speed of $\mathcal{U}^r$ should be not slower than $\beta^r$. Taking $\Phi \triangleq \min \left\{a_1, a_2/\beta^0, a_3, \frac{\mathcal{U}^r}{\beta^r 10\rho}\right\}$, we have

$$
\beta^r \Phi \mathcal{H}^r \leq (\mathcal{P}^r - \mathcal{P}^{r+1}) \\
+ \mathcal{U}^r \frac{\gamma^{r-1} - \gamma^r}{2} \sigma_\lambda^2 + \frac{2\mathcal{U}^r}{\rho} \left(\frac{\gamma^{r-2} - \gamma^{r-1}}{\gamma^r}\right) \sigma_\lambda^2 + (\mathcal{U}^r - \mathcal{U}^{r+1}) \frac{\gamma^0}{2} \sigma_\lambda^2 \\
+ \mathcal{U}^r \left(\frac{\beta^r}{n} \sigma_f^2(T, K) + 4\epsilon_g(T)\sigma_\lambda\right) \left(1 + \frac{4}{\gamma^r \rho}\right) + \mathcal{U}^r \sigma_\lambda^2 + \epsilon_f(T)\mathbb{E}||\nabla f(\bar{\theta}^r, \mathcal{U}^r \lambda^r)|| \\
+ (\mathcal{U}^r - \mathcal{U}^{r+1}) \frac{1}{n} \sum_{i=1}^n \sigma_\lambda \mathbb{E}\|g_i(\bar{\theta}^{r+1})\| \\
+ \left(3 \left(2\kappa + \frac{1}{n}\right) + \frac{L}{n} + 6 \left(1 + \frac{1}{\nu}\right) \kappa + 4L^2 \beta^r \left(1 + \frac{1}{\nu}\right)^2 \kappa\right) (\beta^r)^2 \sigma_f^2(T, K), 
$$

(129)
where $\mathcal{U}^0 = \frac{\rho(\gamma^1)^2}{\rho(\gamma^1)^2 + L(r+1) + L^2 - 1 + \nu}$ and $\|\Lambda^r\|^2 \leq n\sigma^2$.

**Third step:** apply the telescoping sum

Combining with (127), we have

$$
\beta^r E[G^2(\theta^r, \lambda^r)]
\leq \Theta \left( P^p - P^{p+1} + U^0\sigma^2 + \frac{2U^0}{\rho} \left( \frac{\gamma^r - 1}{\gamma^r - 1} - \frac{\gamma^r - 1}{\gamma^r - 1} \right) \sigma^2 + (U^r - U^{r+1}) \frac{\gamma^0}{2} \sigma^2 
+ U^r \left( \frac{\rho\sigma^2(T, K)}{n} + 4\varepsilon_g(T, \sigma^2) \right) \left( 1 + \frac{1}{\gamma^r \rho} \right) \right) + \mathcal{U}^r + \mathcal{E}_f(T) \| \nabla f(\theta^r, U^r, \lambda^r) \|
+ (U^r - U^{r+1}) \frac{1}{n} \sum_{i=1}^n \mathcal{U}^r \| g_i(\theta^r) \|
+ \left( 3 \left( 2\kappa + \frac{1}{n} \right) + L + 6 \left( 1 + \frac{1}{\nu} \right) \kappa + 4L^2 \beta^r \left( 1 + \frac{1}{\nu} \right)^2 \kappa \right) \left( \beta^r \right)^2 \sigma^2(T, K),
+ \left( \frac{4n + 2}{n} \right) \left( \left( 18 \left( 1 + \frac{1}{\nu} \right) \kappa + 3L^2 \right) \left( \beta^r \right)^2 \sigma^2(T, K) \right) \sum_{i=1}^n \mathcal{U}^r \| g_i(\theta^r) \|ight) \beta^r.
$$

(130)

Note that the reward value is bounded (denoted by $G$), so we have

$$
\| g_i(\theta_i) \| \leq \| c_i \| + \left\| \mathbb{E} \left[ \sum_{t \geq 0} \gamma^t C_i(s^t, a^t) | s^0, \pi_{\theta_i} \right] \right\| \leq \max \{ \| c_i \| \} + \frac{G}{1 - \gamma}, \forall i.
$$

(131)

Similarly, since the partial derivatives of the log function of the policies are also bounded, we have

$$
\| \nabla \theta, f_i(\theta_i, U^r, \lambda_i) \| \leq \mathbb{E} \left[ \sum_{t=0}^\infty \left\| \left( \sum_{t=0}^t \nabla \log \pi(a^t_i | s^t_i, \theta_i) \right) \gamma^t R_i(s^t_i, a^t) \right\| - \sum_{t=0}^\infty \left( \sum_{t=0}^t \nabla \log \pi(a^t_i | s^t_i, \theta_i) \right) \gamma^t C_i(s^t_i, a^t, U^r, \lambda_i) \right\|
\leq \frac{G^G(1 + \rho^0 \sigma^2)}{(1 - \gamma)^2} \leq \mathcal{G}^r, \forall i.
$$

(132)

Applying the telescoping sum over (130), gives rise to

$$
\sum_{r=1}^N \beta^r E[G^2(\theta^r, \lambda^r)]
\leq \Theta \left( P^p - P^{p+1} + \gamma^0 U^0 \sigma^2 + \frac{2U^0}{\rho} \gamma^0 \sigma^2 + \mathcal{U}^0 \sigma^2(T, K) + \sum_{r=1}^N \mathcal{T}_2^r + N \mathcal{T}_3^r \sigma^2(T, K) + \sum_{r=1}^N \mathcal{T}_4^r + \sum_{r=1}^N \mathcal{T}_5^r \sigma^2(T, K) \right)
$$

(133)

where

$$
\mathcal{T}_2^r \triangleq \left( \frac{\rho\sigma^2(T, K)}{n} + 4\varepsilon_g(T, \sigma^2) \right) \left( 1 + \frac{1}{\gamma^r \rho} \right) + \sigma^2(T, K),
$$

(134)

$$
\mathcal{T}_3^r \triangleq \left( 3 \left( 2\kappa + \frac{1}{n} \right) + L + 6 \left( 1 + \frac{1}{\nu} \right) \kappa + 4L^2 \beta^0 \left( 1 + \frac{1}{\nu} \right)^2 \kappa \right) \sigma^2(T, K),
$$

(135)

$$
\mathcal{T}_4^r \triangleq \frac{4n + 2}{n} \left( \left( 18 \left( 1 + \frac{1}{\nu} \right) \kappa + 3L^2 \right) \left( \beta^r \right)^2 \sigma^2(T, K) \right),
$$

(136)

$$
\mathcal{T}_5^r \triangleq \frac{4n + 2}{n} \sigma^2(T, K).
$$

(137)
Note that due to the boundness of $A$ we have that $U^rW^r$ is lower bounded, implying that the potential $P^r$ is lower bounded since the rewards are also bounded.

Next, we will have the results of the convergence rate of Safe Dec-PG.

**Fourth step:** the output of the solution is picked randomly, where the corresponding distribution is denoted by $P_r$. Let the probability mass function $P_r$ be chosen such that $P_r = \beta^r / \sum_{r=1}^{N} \beta^r$ for any $r = 1, \ldots, N$. Then, we have

$$
\mathbb{E}[g^2(\theta^r, \lambda^r)] \\
\leq \Theta \sum_{r=1}^{N} \lambda^r + \Theta \sum_{r=1}^{N} \lambda^r \sum_{r=1}^{N} \beta^r + \Theta \sum_{r=1}^{N} \lambda^r \sum_{r=1}^{N} \beta^r + \Theta \sum_{r=1}^{N} \lambda^r \sum_{r=1}^{N} \beta^r + \sum_{r=1}^{N} \lambda^r \sum_{r=1}^{N} \beta^r + \lambda^r. 
(138)
$$

According to Lemma 9, we choose $\beta^r = \beta^0 / \sqrt{r}$, i.e., $O(1/\sqrt{r})$, where $\beta^0 = \min\{\beta_1, \beta_2, \beta_3\}$. By incorporating condition (93), we can select $\gamma^r = 1/\sqrt{r + 5}$, i.e., $O(1/\sqrt{r})$. Then, we have

$$
\sum_{r=1}^{N} \beta^r \sim O(\sqrt{N}), \quad \sum_{r=1}^{N} (\beta^r)^2 \sim O(\log(N)), \quad \sum_{r=1}^{N} \gamma^r \sim O(\sqrt{N}), \quad \sum_{r=1}^{N} (\gamma^r)^2 \sim O(\log(N)).
(139)
$$

In the following, we can quantify the size of each term in (138) respectively:

- Since $\Theta, \Phi, I_1$ are constants, the first term in (138) is decaying in an order of $O(1/\sqrt{N})$.
- From (134) and (95c), we know that

$$
\sum_{r=1}^{N} \lambda^r \sum_{r=1}^{N} \beta^r \sim O\left(\sqrt{N} \left(\sigma^2_g(T, K) + \epsilon_g(T)\right)\right) + O(\log(N)).
(141)
$$

Thus, the second term in (138) is decreasing in an order of $O(\log(N)/\sqrt{N} + \sigma^2_g(T, K) + \epsilon_g(T))$ in total.

- We take $T \sim \Omega(\log(N))$, resulting in $\epsilon_f(T) \sim O(1/N)$. Consequently, the fourth term in (138) is shrinking in an order of $O(1/\sqrt{N})$. Otherwise, the size of this term is $O(\epsilon_f(T) \sqrt{N})$.
- From (136), we know that $\lambda^r \sim O(1/r)$. Hence, the fifth term in (138) is reducing at least in a rate of $O(\log(N)/\sqrt{N})$.
- $I_5$ is a constant, so the size of the sixth term in (138) is $O(\sigma^2_g(T, K))$.

It is clear that the error terms in $I_3, \sum_{r=1}^{N} \lambda^r \sum_{r=1}^{N} \beta^r$ and $NG^r \epsilon_f(T)$ are functions of $\epsilon_f(T), \epsilon_g(T), \sigma^2_g(T, K)$. From Lemma 1 and Lemma 2, we know that when $T \sim \Omega(\log(N))$, the sizes of terms $\epsilon_f(T)$ and $\epsilon_g(T)$ are $O(1/N)$ and the sizes of terms $\sigma^2_g(T, K)$ and $\sigma^2_g(T, K)$ become $O(1/K)$.

In summary, we have

$$
\mathbb{E}[g^2(\theta^r, \lambda^r)] \leq O\left(\frac{\log(N)}{\sqrt{N}}\right) + \sigma^2_g(T, K)
(142)
$$

where $\sigma^2(T, K)$ is a function of $\sigma^2_g(T, K), \epsilon_f(T)$ and $\epsilon_g(T)$. When $T \sim \Omega(\log(N)), \sigma^2(T, K) \sim O(1/K)$. Note that $\sigma^2(T, K)$ is $O(1)$ with respect to $n$.

**Remark 7.** From Theorem 1 it is concluded that Safe Dec-PG converges to a neighborhood of the $\epsilon$-FOSP, where the radius of the neighborhood is in an order of $O(1/K)$. When the batch size is large, the radius of the neighborhood becomes small, which is standard in stochastic algorithms.

**Proof of Corollary 1**

**Proof.** Substituting $K \sim O(\sqrt{N})$ into Lemma 2, we will have $\sigma^2_g(T, K) \sim O(1/\sqrt{N})$ immediately when $T \sim \Omega(\log(N))$. From (142), we can have the desired result. 

$\Box$
Additional Numerical Results

In this section, we provide additional numerical results showing the performance of Safe Dec-PG for the cooperative navigation task created in this work. The parameters of Safe Dec-PG are $\beta^0 = 0.08$ and $\rho = 20$. The length of the horizon approximation is $T = 20$ and the number of independent trajectories is $K = 10$. The topology of the communication network is the Erdős–Rényi random graph with density 0.4, and each node combines its neighbor’s weights equally through matrix $W$. We will depict both rewards in the objective and rewards in the constraints versus the number of iterations. Different from the rewards in the objective function, the rewards in the constrained part are functions of the minimum distance between two agents. Here, the reward at node $i$ in the constraint is constructed as a monotonically increasing function of the minimum distance between each node and its neighbors. Therefore, the safety constraints considered in this case are written as $J^C_i(\theta_i) \geq c_i, \forall i$ and the average reward is $n^{-1} \sum_{i=1}^{n} J^C_i(\theta_i)$. The experiments were run on the NVIDIA Tesla V100 GPU with 32GB memory.

**Safe Dec-PG v.s. centralized PG without safety concerns**

![Graph 1](image1.png)

**Figure 2:** Reward v.s. number of iterations, where $c_i = 1.4, \forall i$.

In this section, we compare Safe Dec-PG and the centralized case without the safety long-term cumulative reward considerations where $n = 5$. From Figure 2(a), it can be observed that Safe Dec-PG outputs higher averaged constrained rewards as it converges compared with the case where there are no safety concerns introduced. Further, it can be seen from Figure 2(b) that Safe Dec-PG achieves a similar convergence rate but a slightly higher objective reward than centralized PG. The reason would be that adding the long-term reward constraint is more or less equivalent to introducing some prior knowledge on avoiding the collision.

![Graph 2](image2.png)

**Figure 3:** Decentralized and centralized implementation of Safe Dec-PG, where $c_i = 1.2, \forall i$. 

![Graph 3](image3.png)
Then, we further compare the convergence rate of Safe Dec-PG with its centralized counterpart. In general, when an algorithm is implemented over a network, it needs more number of iterations to achieve the same accuracy compared with its centralized counterpart. The reason is that the consensus process may take some extra iterations so that each agent can learn enough information from its neighbors. In this case, it can be observed that Safe Dec-PG has almost the same performance as its centralized counterpart, indicating implementing Safe Dec-PG over a graph is as good as the centralized processing. This implies that the inaccurate PG estimate and the shapes of the objective and constraint functions dominate the performance of the algorithm rather than the weights disagreement (or consensus violation). From another perspective, it is suggested that in this case the PG or gradient tracking technique makes the consensus process of the algorithm very efficient as illustrated in the literature (Tang et al. 2018; Lu et al. 2019; Chang et al. 2020) so that the consensus error is in orders of magnitude smaller than other errors that affect the convergence behaviors of the algorithm.

Different desired bounds in the constraints

Further, we show in Figure 4 the convergence behavior of Safe Dec-PG with respect to different desired bounds of the constraints. It is clear from Figure 4(a) that the larger the constants $c_i$ are, the higher the rewards will be achieved from a long-term perspective, which is expected. The rewards obtained in the objective in these three cases are similar, where the rewards achieved in the case $c_i = 1$ are slightly lower than in the other two cases at the beginning. The reason is that introducing this constraint may affect the searching space of the algorithm so that the convergence rate empirically becomes slower. Hence, we comment that adding a (probably large) $c_i$ does not imply that the constraints will always help in improving the convergence performance. In this work, it is by no means that Safe Dec-PG will give a higher achievable reward for maximizing the objective function.
compared with other existing works. But it is desired that the safety constraints can be incorporated in the MARL systems.

**Safe Dec-PG v.s. DSGT on Larger Network**

Additionally, we also compare the Safe Dec-PG and DSGT without safety constraints on a larger network with $n = 10$ agents, where the communication graph is again randomly generated. It can be seen from Figure 5 that Safe Dec-PG can achieve high constrained rewards and even with relatively higher objective rewards. This observation indicates that the advantages of Safe Dec-PG will not be affected by increasing the number of agents, which is consistent with our theoretical analysis.

From the above numerical results, we conclude that Safe Dec-PG is able to solve decentralized safe problems both effectively and efficiently, shedding light of implementing the safe RL algorithm over graphs.
